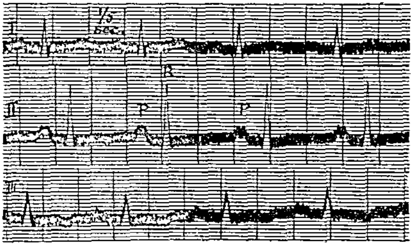
Osler and McCrae[5] say that this remarkable condition may follow pericarditis, especially the suppurative and tuberculous forms, and that A. E. Jones's careful study shows that the condition is usually latent and unrecognised. Allbutt and Rolleston[6] mention that an adherent pericardium may undergo calcification; that "there seems to be good reason to believe that a purulent collection in the pericardium may in exceptional instances be absorbed, leaving dense and thick adhesions, or some of it may remain in an inspissated condition as a yellowish white paste, limited and encapsuled by adhesions consisting of caseous material in which calcareous particles may afterwards form." They describe it as a condition that may follow chronic pericarditis in extremely exceptional instances, and say that the pericardium may become a completely calcified shell, and may even encroach upon the cardiac walls, constituting the so-called "bony heart." They mention that it has been affirmed that a calcified pericardium may give rise to a peculiar percussion sound of an osteal quality. Turner describes pericardial calcification as a rare pathological finding. He found 89 authenticated cases in the literature; most of them were discovered at autopsy. Turner diagnosed one clinically and found two others post mortem. In his first case the apex-beat was not visible, no shock nor thrills were present, nor could the apex-beat be detected by palpation. The heart sounds were distant and feeble, but no murmurs were audible; the cardiac dullness extended three fingers to the right of the mid-sternal line and four to the left. The radial artery was sclerotic. The patient was sent to the X ray department. Ultimately the diagnosis of marked fibrosis of the right lung and calcification of the pericardium was made.

FIG. IV.



Electrocardiogram from case of calcification of the pericardium.

Absence of Symptoms.

The absence of symptoms is noteworthy and most authors point it out. Schlesinger[7] mentions that most of the cases of pericardial calcification are characterised by their symptomless development, their frequency in early adult life, and the freedom of the great vessels from involvement. Failure of the heart is late and probably due to other causes, and there is often ascites. An unusual symptom of the condition was found in a case, described by Wallace Jones and Roberts[8] in 1927, where the patient, a young man, had dyspnœa and marked cyanosis, the former being relieved by rest but the latter not improved by inhalation of oxygen. They gave an electrocardiogram of their case. The heart does not appear to become embarrassed, despite what would be expected and has been taught; it seems to go on performing its functions satisfactorily for many years, in some cases for 10 or 20 years.

A. E. Jones, quoted by Osler and McCrae, found that no cardiac symptoms were present in 38 of his 59 collected cases. In only one of the 59 was adherent pericardium diagnosed, and calcification was not suspected in any (Turner). Mitchell[9] remarks, "How is it that the heart, encased in a vice-like grip, functions with apparently so little disturbance?" It is indeed surprising. In my case the apex was functioning freely. Turner mentions that in Drummond's case the pathologist had to use bone forceps to cut the pericardium, but a few weeks previously the man had been a sailor working before the mast. In Douglas and Yates's case the patient was 25 when he died of pneumonia, and the condition discovered post mortem had been totally unsuspected (Turner). Although X rayed before death, the case reported by Langmead[10] in 1912 had not been recognised radiologically, the report stating that "the shape of the heart is most peculiar. There appears to be a protuberance from the left ventricle near the apex, pulsation of which appears to be more vigorous than that of the ventricle, and its walls are thinner. The appearance suggests aneurysm of the left ventricle." In 1917 Mueller[11] emphasised that his eight cases had in common the entire absence of clinical findings which might suggest calcification of the pericardium, but he mentions the success of Rieder, Groedel, and Schwartz, all of whom made a radioscopic diagnosis of the condition in a living subject. Turner says that in none of his patients was there any marked clinical symptoms pointing to a serious heart condition, but the X rays in one case enabled a diagnosis of calcified pericardium to be made, and this was confirmed post mortem. In the other two cases, where X rays were not employed, the diagnosis was not made before death.

Stone[12] mentions that adhesions between the visceral and parietal layers of the pericardium may produce little disturbance of heart function "even when more or less obliteration of the pericardial cavity has occurred, provided the heart's contractile efforts are unimpeded by extrapericardial adhesions to the chest wall and surrounding structure of the mediastinum." When this occurs there follow certain signs and symptoms which he enumerates, and among which is rotation of the heart towards the back, accompanied, according to his observations, by a friction-rub synchronous with the heart's action below the angle of the left scapula and possibly not heard over the anterior portion of the chest. He shows a radiograph of a case of pericarditis and mediastinitis. He further mentions that under the fluoroscopic screen diminished pulsating excursions of the cardiac shadows may occur, and that the deposition of lime salts in the connecting tissue after chronic inflammation is not an unusual pathological finding. Although it may occur in the endocardium or myocardium, the pericardium is usually more extensively involved. He adds that the clinical signs and symptoms may be inconclusive, and that the main evidence will be radiological. Under X rays fixation of the apex and the failure of the apex to descend upon inspiration may occur. Cutler and Sosman emphasise the importance of careful radioscopic and radiographic examination in all cases suspicious of adherent pericardium, especially because the clinical diagnosis is unlikely to be made with certainty and further because the operation of cardiolysis and excision of the pericardium is followed by favourable results. Stone puts forth a similar view.

The honour, or good fortune, of being the first to record a case of pericardial calcification rontgenologically appears to be in dispute. According to Stone, Schwartz, in 1910, was the first to show a case of calcified pericardium during life by radioscopy. Starck[13] also mentions this, and Groedel described one in 1912. Scholz[14] mentions a case of myocardial calcification demonstrated during life. He says that there are only two previous instances on record—viz., the cases of Groedel and Le Wald. In neither of these cases was an autopsy obtained, so that no final decision can be given on whether the findings described by the authors were due to calcification in the myocardium or pericardium. He therefore claims that his case is the first authentic one. Cases of pericardial calcification were described by Rieder, Weil, Müller, Heimberger, Youmans and Merrill, Klason Zelibe, and others. The discovery of the cases was sometimes a chance and sometimes induced by the presence of slight heart failure, or of Pick's pericarditis of the pseudo-liver-cirrhosis type.

The principal point in the differential diagnosis between pericardial and myocardial calcification is that the flakes of calcium will be seen tangentially in the pericardial condition, and for that purpose antero-posterior and lateral views should be taken. Scholz recommends the use of intensifying screens, and rapid yet sufficient exposures to show the plaques. The Potter Bucky diaphragm can be used to increase the contrast of shadows, but the sharpness of outline of the beating heart is sacrificed.

In the case described I used a teleradioscope, taking the films at a distance of 2½ metres. Unless the radiologist is aware of the condition it can be missed in a hasty screening, especially as the usual soft radiations employed for the detection of pulmonary lesions only show the outline of the heart and cast no obvious contrasting shadows of the heart substance itself.

My thanks are due to Mr. Hugh Lett, to whose courtesy I am indebted for permission to publish this case, and to Dr. John Parkinson, who saw the case with me later and took the cardiogram.

DISSEMINATED ENCEPHALOMYELITIS FOLLOWING SMALL-POX:

WITH REPORT OF A FATAL CASE.

BY ARTHUR G. TROUP, M.D. ABERD., D.P.H.,
MEDICAL SUPERINTENDENT, WILLESDEN MUNICIPAL HOSPITAL;
AND
E. WESTON HURST, M.D., B.Sc. BIRM.,
RESEARCH PATHOLOGIST TO THE MILBANK FUND FOR POLIOMYELITIS RESEARCH, BACTERIOLOGICAL DEPARTMENT, LISTER INSTITUTE OF PREVENTIVE MEDICINE.

(WITH ILLUSTRATIONS ON SPECIAL PLATE.)

AS a result of the attention paid during recent years to the disseminated encephalomyelitis following vaccination, the peculiar character of the lesions, as well as the fairly distinctive clinical features of many of the cases, have become common knowledge. It is not, however, generally known that a similar complication may arise in the course of measles, small-pox, and other infective fevers, or even during antirabic treatment. The encephalomyelitis of measles has been very fully studied by Greenfield (1929) and others, and it is clear that the histological lesions in these cases are indistinguishable from those of the post-vaccinal disease. While, however, there are to be found in the literature a few cases of encephalomyelitis following small-pox in which the descriptions are sufficiently precise to allow of their probable identification with the disease under discussion, the accounts are for the most part very incomplete, and in any case date back to a time when the characteristic histological feature—namely, perivascular demyelination—was unrecognised. The following case, therefore, appears to merit description.

Clinical History.

The patient, an unvaccinated man aged 63, was admitted to the Willesden Small-pox Hospital on June 7th, 1929, the ninth day of illness and the fifth day of rash. He had attended a wedding party on May 19th at which an unrecognised case of small-pox (alastrim) was also a guest. Fifteen other people were infected either directly or indirectly from the same source but no complications arose amongst these associated cases. The rash was discrete, typical in distribution, and in the pustular stage. The temperature was normal and the pulse-rate 76. The eyes were inflamed and discharging. The general condition was good.

On June 10th he complained of slight pain in the right knee, but examination failed to reveal any abnormality, and he was able to get up for baths. On the 13th he asked for permission to get up, which was granted. During the night of the 13th–14th he slept well, but on the morning of the 14th he complained of severe pains in the abdomen and legs, the former appearing to be of the girdle type. The temperature rose to 101° F. and he had several rigors with profuse sweating. There was retention of urine, the bladder reaching to nearly the level of the umbilicus, and it was thereafter necessary to pass a catheter twice daily until his death.

On the next day complete flaccid paralysis of the lower extremities with involvement of the abdominal muscles had developed. The knee-jerks, the plantar and the abdominal reflexes were absent. Tactile, thermal, and pain sensations were very much impaired and later were lost. The pupils were contracted and reacted sluggishly to light and accommodation. The temperature rose to 104° F. and there was a recurrence of the rigors. The pulse was 122, regular, and of good volume. The heart sounds were feeble and there were signs of congestion at the bases of the lungs. The paralysis did not at this time affect the upper extremities, though later there was considerable diminution of muscular power in the arms, so that the patient could not feed himself. He was very drowsy and did not appear to understand what was said to him. On the following day he complained of severe headache and there was albumin in the urine. It was also noticed that the skin over the sacrum was affected; a large bed-sore subsequently developed, the tissues becoming gangrenous.

Incontinence of fæces developed on June 17th; before this the patient had been constipated. From this date until the patient's death there was gradual muscular wasting, more particularly in the lower extremities. The temperature ranged between normal and 102·6° F., falling in the morning and rising in the evening. The physical signs at the bases of the lungs became more pronounced and a troublesome cough developed. There was great difficulty in expectoration, due to paralysis of the intercostal muscles and to the viscid character of the sputum. The mental condition varied; occasionally the patient was in a comatose condition but capable of being roused; at other times he was alert and able to answer questions in an intelligent manner. On several occasions, particularly during the night, he had delirium of a low muttering type. On June 28th a painful swelling developed in the neighbourhood of the right parotid gland but subsided within five days. Evidence of cystitis was noticed on July 4th. Death took place on the ninth.

Specimens of the cerebro-spinal fluid and blood were taken on June 20th. The former was under slight pressure, but examination showed no abnormality. Wassermann tests with cerebro-spinal fluid and with blood proved negative.

Pathological Examination.

As permission for a full autopsy was not secured, only the brain and spinal cord were examined. The middle and lower lumbar and sacral cord was reduced to a very soft, greyish-pink mass and could not be removed except as a pulp; elsewhere the nervous tissue was of normal consistence and no other macroscopic abnormality was noted.

After pieces had been placed in formol bromide, to be cut later as frozen sections and stained by Penfield's modification of the Hortega method for microglia, the bulk of the brain and cord was fixed whole in 10 per cent. formol saline. Tissue was later embedded in celloidin and sections were stained with *hæmatoxylin and van Gieson and by the Nissl method.* Other blocks were mordanted and sections stained by the Weigert-Pal procedure. Finally frozen sections were used for the demonstration of fat and of neurofibrils by the Bielschowsky technique.

Description of Lesions.

Microscopically the lesions consist partly in perivascular infiltration and partly in changes (extra-adventitial) in the nervous tissues immediately surrounding the vessels; in all the affected parts of the nervous system this association of the pathological changes with the vascular apparatus is observed.

Perivascular infiltration—that is, the accumulation of cells in the Virchow-Robin spaces—is usually not very intense. In the case of many vessels, only a few cells, insufficient to produce a complete ring around the vessel, are present, while in others the cuff is more complete; perivascular sheaths several cells deep are, however, nowhere observed. Occurring as a rule in vessels surrounded by zones of demyelination, in a few regions this infiltration occurs in the absence of other changes. Lymphocytes, large and small, with occasional plasma cells, form a small percentage of the cells present, but the majority are granular corpuscles which, in sections stained for fat, are seen to be heavily laden with the lipoid products of myelin disintegration.

The extra-adventitial lesions are characterised by zones of demyelination, which in severely affected regions such as the spinal cord are very extensive and often coalesce with the similar areas around adjacent vessels. In Weigert-Pal preparations the inner two-thirds of these zones are usually wholly free from myelin sheaths, while the outer third, in which the majority have been destroyed, may show a few persisting but ballooned and distorted myelin tubes (see Plate, Fig. IV.). At the periphery of this zone, which with the lower powers of the microscope is quite sharply demarcated, the myelin sheaths are normal.

Corresponding to the destruction of the myelin sheaths, there is, immediately around the vessels, considerable cellular infiltration, which in sections stained by the ordinary tissue stains is the most prominent feature (Figs. I. and II.). Most of the cells are microglial, in various stages of development up to the fully formed granular corpuscle. While showing a certain polymorphism, their nuclei do not exhibit the excessive irregularities and grotesque forms seen in the acute cases of the similar condition following vaccination; this is no doubt due to the fact that the present case was of much longer duration and had progressed to a stage of partial reparation. Their bodies are filled with fatty globules. While, however, there is much fat in these cells and in the similar elements in the Virchow-Robin spaces, the total amount is often small when compared with the extent of the demyelination; the observation made in post-vaccinal encephalitis that the waste lipoid products are removed from the damaged area with unusual rapidity seems equally to apply to the present case.

The other type of cell present in the demyelinated areas is a definitely enlarged glial cell with a large pale nucleus and abundant cytoplasm prolonged into numerous short processes; no fibre formation can at this stage be demonstrated. Leucocytes, of any variety, are absent from most of these areas, though here and there in the grey matter of the spinal cord a few focal collections of lymphocytes occur.

The use of the Bielschowsky method shows that a few axis-cylinders persist in the zones of demyelination; their number is, however, far below the normal and, of those that remain, many are thickened and stain more intensely than usual or show numerous fusiform, globular, or irregular swellings in their course.

Throughout the nervous system the nerve-cells are remarkably well preserved, and even when involved in a densely infiltrated area present no definite changes in their Nissl substance or in the shape, coloration, and position of the nucleus.

Distribution of Lesions.

Spinal cord.—The brunt of the morbid process has fallen on the spinal cord, though not equally on all regions; the transition from a severely damaged to a slightly affected or even normal segment is often very abrupt. As already stated, much of the lumbar region was so soft that sections could not be prepared. In the segments immediately above this region the changes are very intense and at first sight not obviously perivascular; owing to the fusion of many zones of infiltration and demyelination, the lesions appear to be more or less diffuse over a wide expanse of grey and white matter. There is considerable rarefaction of the tissues and large spaces appear in the sections: present even in frozen sections, they are not due to shrinkage in the celloidin or paraffin, and they are not filled with fat (Fig. I.). Microglial and glial proliferation is very prominent. A few mononuclear cells are present in the anterior fissure.

In the dorsal cord the extent of the lesions varies greatly at different levels, but no segment examined has completely escaped; the mid-dorsal segments are perhaps least affected, while in the lower dorsal region almost every vessel in the white matter shows a wider or narrower zone of rarefaction and infiltration. Perivascular cuffing is more definite than in other parts of the nervous system. Both grey and white matter is involved, and though at some levels the antero-lateral regions have suffered most, at others the posterior columns are also the seat of marked changes. In the middle and lower cervical cord similar severe changes are seen; the upper cervical segments are free from lesions.

At no level is the narrow zone of demyelination, not infrequently met with in post-vaccinal encephalitis, observed in the marginal zones of the cord or along the lips of the anterior fissure.

Brain-stem.—Except at the lower end of one olive, where a single vessel is surrounded by a wide zone of infiltration, the medulla is quite free from the typical lesions; a few vessels do, however, show simple perivascular cuffing of mild degree. The disease reappears in moderate intensity in the pons, where the central substance is chiefly affected, but almost disappears again when the mid-brain is reached.

MALIGNANT CHANGE IN A CHRONIC DUODENAL ULCER.

BY E. H. KETTLE, M.D., M.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.

(WITH ILLUSTRATIONS ON SPECIAL PLATE.)

PEPTIC ulceration of the stomach and duodenum is a common disease which, fortunately, appears to be amenable to medical treatment, at least in the majority of cases. Even long-standing ulcers of considerable extent can be coped with satisfactorily without resort to operative measures. But a question which must have a serious bearing on treatment is the relation of peptic ulceration to malignant disease. For if it can be proved that the frequency of carcinoma is significantly greater in the ulcerated than in the non-ulcerated stomach, the wisdom of medical treatment becomes immediately open to question, and the arguments in favour of excision of the ulcer are correspondingly strengthened.

Malignant Change in Gastric Ulcers.

Opinions are still divided as to the number of gastric ulcers which become malignant. On the one hand there is the teaching of the Mayo Clinic[1] who find malignant change in 71 per cent. of gastric ulcers; on the other is the statement of J. Ewing,[2] whose figures are in the region of 2–3 per cent. A. F. Hurst and M. J. Stewart,[3] in a series of 180 chronic gastric ulcers, found malignant disease in 6·1 per cent., and have only once found evidence that a carcinoma started in the scar of a healed ulcer. These discrepancies are no doubt due to differences in the criteria both of malignancy and previous ulceration demanded by different observers.

Evidence of malignancy must be unequivocal and must not merely consist of the presence of misplaced epithelium in the margins of the ulcer; while the proof that an ulcer preceded a carcinoma depends partly on the clinical history of the patient and partly on the histological features of the growth. A history of dyspepsia of long standing is of obvious importance, but this is not always forthcoming even in authentic cases of ulceration. On the other hand, a searching cross-examination of many apparently healthy individuals may bring to light symptoms which may be interpreted as pointing to a gastric or duodenal ulcer. Clearly the value to be placed on the clinical history must depend largely on the experience and judgment of the physician.

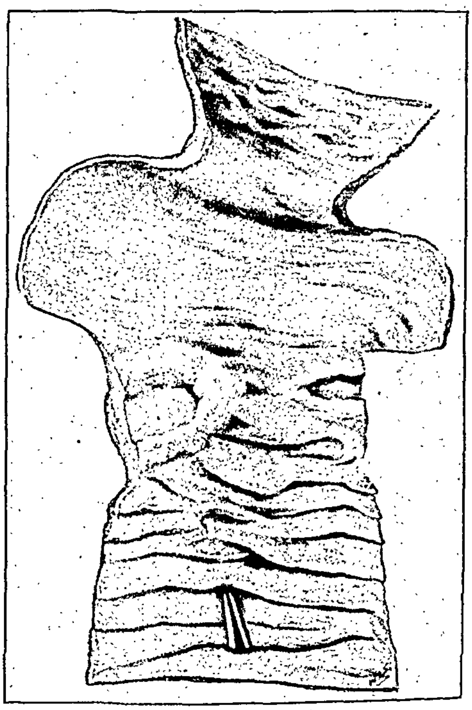
The histological diagnosis is possibly easier. In the chronic gastric ulcer the muscle coat in the floor of the ulcer is invariably destroyed and is replaced by dense inflammatory fibrous tissue, and a patchy though notable endarteritis is frequently found in the neighbouring vessels. In the primary cancer, on the other hand, the tumour cells infiltrate the muscle coat of the stomach which survives in the substance of the growth until that has become so large as to make the recognition of the primary lesion impossible. And endarteritis and other signs of inflammation are much rarer in the primary carcinoma than in the ulcer-cancer.

Irritation and Malignancy.

Whether the gradual destructive processes which produce the chronic peptic ulcer are comparable with those irritative conditions which are known to determine the occurrence of malignant disease in, for example, the skin, is open to doubt. In the cancer which can be produced experimentally by the application of tar to an epidermis, the malignant process is usually preceded by a simple, non-malignant proliferation of the epithelium; and the same is seen in the carcinomata of the skin familiar in certain industrial conditions. Excessive application of the irritant causes ulceration and is not followed by the production of carcinoma. In the peptic ulcer the *process is essentially a progressive digestion of tissue*; there may be slight hyperplasia of the epithelium at the margins of the ulcer, but this is rarely extensive, and there is nothing like the irritative hypertrophy which follows the application of true carcinogenetic substances, or even foreign bodies such as *Gongylonema neoplasticum.*

If peptic ulceration has any power at all to determine the development of carcinoma it is probably because of the separation and isolation, by the proliferating fibrous tissue at the margins of the ulcer, of small fragments of epithelium. This being so, it might be expected that peptic ulcer of the duodenum would also be the forerunner of malignant disease, for except in one particular, though possibly a very important one, the process in the duodenum is essentially the same as that in the stomach. The sole difference is the additional trauma to which the gastric ulcer is exposed from solid, imperfectly masticated food. But ulcer-cancer of the duodenum is excessively rare.

FIG. I.



Pylorus and duodenum opened from the front. *Glass rods in* the pancreatic and common bile-ducts appear at the ampulla of Vater (× ½).

In a series of autopsy records collected from various sources, J. B. Deaver[4] found 50 examples of carcinoma of the duodenum in 151,201 cases, and states that 30 of these arose in ulcers. It may well be that a more rigid examination of these 30 cases would demand the elimination of a number of them. The current teaching in this country is that ulcer-cancer of the duodenum is little more than a possibility. Hurst goes so far as to say that duodenal ulcers never become malignant, and though this is a statement which it is theoretically impossible to support, most people will agree that it expresses a good working rule.

Record of a Case.

The case here recorded is regarded as a true example of a duodenal ulcer-cancer; it illustrates well the difficulties which have to be met in arriving at the diagnosis.

The patient, a man aged 68 years, was admitted to St. Bartholomew's Hospital on Nov. 29th, 1929, complaining of vomiting. He was very ill and was inclined to wander, and the history of his illness was difficult to obtain. He is said to have suffered from vague pain in the upper abdomen with dyspepsia for three years. During the latter half of 1928 there was persistent and rather severe diarrhœa and in the beginning of 1929 flatulence and dyspepsia, starting two and a half hours after food and lasting for an hour, became more pronounced. The pain increased, and five months before admission to hospital vomiting became a prominent symptom, increasing till it was almost continuous. While in hospital he could retain nothing given by the mouth, and it was impossible to investigate him thoroughly. An X ray examination showed that the barium meal hesitated to pass into the second part of the duodenum, which never became properly filled; but no further tests could be made, and he died on Dec. 3rd, four days after admission, with the tentative diagnosis of carcinoma of the stomach. At the post-mortem examination on Dec. 4th the body was found to be extremely emaciated. There was a moderate degree of terminal hypostatic pneumonia, but no other morbid change was found, except in the stomach and duodenum.

The stomach was dilated and contained two and a half pints of fluid. Its wall was slightly hypertrophied, its mucous membrane was smooth, and showed no trace of old or recent ulceration. Similarly, the first part of the duodenum was dilated and hypertrophied, though its mucosa appeared natural.

Situated about 4·5 cm. from the pylorus and midway between it and the ampulla of Vater was an annular ulcer which surrounded the bowel, except for a small area behind (Fig. I.). The actual ulcer measured 3 by 1 cm., but its margin was thick and raised especially on the posterior and upper aspect, where a firm mass of growth extended for at least 1 cm. beneath the mucosa. The floor of the ulcer was smooth and clean, and it did not involve the head of the pancreas or the common bile-duct. Two small white glands were found in the gastro-hepatic omentum.

Microscopic examination shows an adenocarcinoma, involving the whole of the periphery of the ulcer and extending to the peritoneal coat. The two lymphatic glands contain secondary growth which shows a pronounced tendency to mucoid degeneration and has very little stroma.

Histological Evidence.

The condition, then, is undoubtedly malignant, and the histological evidence that the carcinoma started in a simple ulcer seems equally clear. The centre of the ulcer (see Plate, Fig. II.) is composed of dense fibrous tissue which extends to the peritoneal coat. The muscle coats have been entirely destroyed, though they appear abruptly again beneath the mucosa at the margins. The fibrous tissue is fairly well vascularised and some of the smaller arteries show well-developed endarteritis (Fig. III.). At the periphery the submucosa and muscle coats are invaded by the carcinoma, but the ulcer itself is free except for a few acini which are spreading from the margin into the centre towards the surface. A large portion of the ulcerated area, therefore, contains no growth; and unless we are to believe that the primary lesion was an intensely scirrhous carcinoma in which the growth of the stroma enormously outstripped that of the malignant cells, an hypothesis entirely at variance with the histology of the rest of the tumour and its metastases, we are forced to the conclusion that a peptic ulcer existed before the development of the carcinoma.

It must be admitted that the position of the lesion is against this view, since the great majority of peptic ulcers are situated considerably nearer the pylorus; and the clinical evidence of long-standing ulceration is not conclusive. The histological evidence, however, seems strong enough to outweigh these objections, and viewing the case as a whole it seems justifiable to accept it as an example of ulcer-cancer.

In view of the frequency of ulceration of the duodenum it is remarkable that so few undoubted cases of ulcer-cancer have been recorded. Their scarcity strongly supports the view of those who hold that there is nothing inherent in the peptic ulcer which predisposes to malignancy, but that cancer develops in an unhealthy rather than an ulcerated epithelium.

I am indebted to Dr. H. Morley Fletcher, under whose care the patient was while in hospital, for permission to publish the records of the case.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society on March 10th, with Mr. DONALD ARMOUR, the President, in the chair, a discussion took place on

CARDIAC INFARCTION.

Dr. J. W. MCNEE, in opening, said this subject was of the greatest clinical interest, both to the general practitioner and the physician or surgeon. He would himself deal with it as a general physician. Until 1924 he knew nothing about cardiac infarction as a part of clinical medicine, though he had seen and made necropsies on well-marked cases, and even on cases of cardiac aneurysm with rupture of the ventricle. But while he was at Johns Hopkins Hospital, Baltimore, in 1924, he had the opportunity of studying closely three typical examples of coronary thrombosis and its clinical syndrome. Apparently there was a considerable American literature on the subject. In 1925 he wrote about the condition in this country, and later Dr. John Parkinson and Dr. Evan Bedford did likewise.

When the clinical syndrome and its variations became known a number of instances were recorded; he had seen four cases in the practice of a single general practitioner. He was sure that the question of coronary thrombosis would often arise as a problem of diagnosis in general medicine, or even in general surgery, in patients in whom there had been no previous reason to suspect disease of the heart or vascular system at all. As to the reason this important cardiac disease had been so long missed out of text-books in this country, and by clinical teachers, he thought it was because such great teachers as Mackenzie, Allbutt, and Osler did not separate coronary thrombosis from angina pectoris. It was clear from the books of Clifford Allbutt that many of the cases included by him as "status anginosus" were really instances of coronary occlusion. Yet it was very important to distinguish coronary thrombosis from angina pectoris, because course and prognosis differed so widely. Typical angina pectoris was a fairly frequent precursor of coronary thrombosis, but after the thrombosis all further true anginal attacks usually ceased. The anterior descending branch of the left coronary artery was the vessel most commonly thrombosed; this branch carried blood to the apex of the left ventricle, the left anterior third of the right ventricle, and part of the interventricular septum. Hence thrombosis in it caused an infarction involving both the left and the right cavities of the heart, and mural thrombi occurring on the infarcted area might pass as emboli either to the lungs or to the systemic circulation. Levine had shown that the predisposing causes of coronary thrombosis were the conditions which brought about arterial degeneration; certainly a part, too, was played by a hereditary tendency to arterial disease. Angina pectoris was a common precursor. The male sex suffered from coronary occlusion rather more than the female. Rarely was it seen before the fortieth year.

Trendelenburg position depends upon whether a short or long column of solution has been created within the dura. Inconvenient spread may take place from a large injection even if only slightly hyperbaric. An isobaric solution will stay where it is put.

Behaviour of a Hypobaric Solution.—These solutions have revealed for the first time the characteristic action of a genuine "light" solution. The condition which results in the dorsal decubitus is a preponderating anterior root block with little or no effect on the posterior roots, thus the entire abdominal musculature may be paralysed, yet the patient will be in an inoperable condition unless a general anæsthetic is given. This effect is also recognisable when towards the end of a long operation the patient feels pain but no rigidity accompanies it, and closure of the wound in the abdomen is effected without difficulty. Another demonstration is the greatly exaggerated peristalsis amounting to spasm, due to the more effective paralysis of the efferent inhibitory fibres of the splanchnics contained in the anterior roots. All this occurs in spite of the fact that sensory fibres are more easily affected than motor fibres. It is thus evident that the percain solution has applied itself in greater concentration to the anterior roots than to the posterior. This preponderating anterior root effect is in striking contrast to the preponderating posterior root effect of the small volume heavy solutions spread by gravitational diffusion, and shows a reversal of results. It is therefore necessary when using hypobaric solutions to put the patient in the ventral decubitus after injection in order to soak the posterior roots and develop analgesia, and when he is finally turned on his back the anterior roots will be affected and muscular paralysis follows. He is safe from spread when prone, for the neck will be lower than the upper dorsal region; but when turned on his back the slight Trendelenburg position should be adopted for a time as a precaution. As it is impossible to know beforehand the specific gravity relationship of the normal saline solutions, it will probably be better practice to use in all cases the definitely hypobaric 0·5 per cent. saline solutions (spec. grav. 1·0034) in all strengths of percain, never omitting the technique of the grill-room chef. Strictly limited caudal blocks are possible with small volume hypobaric solutions of percain, which may be used in higher concentrations for this purpose, relying on dilution in the cerebro-spinal fluid but even 6 c.cm. of 1–1000 solution between L4 and L5 may leave the greater part of the lumbar plexus unaffected. These effects of hypobaric solutions constitute a strong criticism of the pseudo-hypobaric spinocain, which although of low specific gravity in the ampoule, can only act in the same way as a heavy solution when mixed with cerebro-spinal fluid, and the clinical results of which are eloquent of gravitational diffusion—viz., preponderating posterior root effect and diminishing concentration from below upward.

General Effects of the Injection.—There is a fall of blood pressure due to vaso-motor paralysis. The fall is not nearly so great as after large doses of novocain, and this is because the high dilution of percain renders sudden absorption into the blood stream impossible. Novocain collapse is due chiefly to general poisoning by the drug following rapid absorption from the more concentrated solutions necessary for effective results. The percain patient, therefore, remains in much better condition on the operating table than those who have had novocain. Ephedrine gr. 1 to 1½ may be given in all cases. Analgesia can be obtained which outlasts the longest abdominal operation.

Respiratory Failure.—The phrenic nerve roots are not likely to be reached directly by these volume doses. Central failure is a possibility which must be watched for especially toward the end of a long operation. The more effective paralysis of the anterior roots of the intercostal nerves results in pure diaphragmatic breathing, and a virtual impediment to respiration causing fatigue of the centre. Shallow breathing, imperfect ventilation of the lung, and anoxæmia operate as a vicious circle progressively increasing central fatigue and tending to arrest. If narcotics have been given this tendency will be much greater. Carbon dioxide and oxygen is the correct treatment, and any dusky colour in the patient is an indication for oxygen. If a combined general anæsthetic is used the closed method with oxygen is an insurance against respiratory failure. Failures with percain will be failures of technique. After-effects are the usual symptoms of "meningism," headache, and vomiting experienced occasionally after other drugs and even after simple puncture.

There have been no disastrous consequences from percain injections, said Dr. Howard Jones in conclusion, and there is little reason why there should be. The maximum dose of 20 mg. required in the spine compares favourably with the 100 to 200 mg. used in the tissues, and 7·5 to 10·0 mg. are more effective than 150 mg. of novocain.

MEDICO-LEGAL SOCIETY
AND
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT *a joint meeting of these Societies held at* 11, Chandos-street, on March 7th, Lord RIDDELL, President of the Medico-Legal Society, took the chair, and a discussion on

THE DOCTOR IN THE LAW COURTS

was opened by Sir WILLIAM WILLCOX. A medical practitioner, he said, might be called as an ordinary or as an expert witness. Even in the former case he was often asked to give an opinion; he should always ask to be excused if he was not absolutely sure of his ground, and the judge would probably support him. In giving evidence of fact he should avoid technical terms as far as possible, and should not make comments. The expert's true function was to assist the court, and he should be absolutely free from bias; this was supremely essential in criminal cases. Before coming to court he should study carefully the most recent literature of the subject; turn and turn over in his own mind every aspect of the matter, and cross-examine himself as severely as possible from the point of view of the other side. Written reports should contain nothing that the witness might have to repudiate afterwards. Sir William was strongly in favour of a separate preliminary conference between the experts called on each side, to clear up doubtful points and enable them to arrive at complete agreement. This was of great help to the court. Answers to cross-examination should be as concise and clear as possible, and the witness should avoid long explanations and evasion of the direct answer. Where he could not answer yes or no, he should give his reasons clearly and courteously. If the question were multiple, he should, if necessary, ask that the component parts of it be put separately. When statements in books or reports were put to him, he should ask to see the document before replying. An expert witness was usually required to attend in court during the whole case, for it was sometimes necessary to question him on his opinion concerning the evidence in general. Coroners' courts admitted much hearsay evidence, but the doctor should refrain from giving it. On the question of professional secrecy, Sir William thought that the confidences of a patient were sacred. They should only be divulged on the direct order of a judge, and then only under strong protest. Finally, the medical witness should not try to introduce points from his report that his counsel did not raise; there might be a special reason for the omission.

Privilege.

Lord RIDDELL said that many doctors envied the lawyers what they believed to be their privilege. The lawyer was not entitled to any privilege; the privilege was that of the client. He alone might say what his lawyer might or might not disclose. This right, however, was very limited, and did not protect a client charged with a crime. A maxim that Sir William had not mentioned was "He who vegetates in the witness-box is lost." The professional witness must have all his wits about him, and it was also a great advantage to look simple and honest. Moreover, a good-tempered witness was very difficult to shake, but one who was conceited or vain was in considerable danger.

Sir William Collins remarked that the Regulations made under the Venereal Diseases Act had laid down that information conveyed by the patient to the doctor should be absolutely confidential and privileged; a doctor had nevertheless been compelled by the judge to violate such a confidence. He himself should have preferred to resist, even to the point of being committed for contempt of court. The reason why priests were never required to reveal the secrets of the confessional was that they would certainly choose the alternative of imprisonment. The judge should have the right to the doctor's evidence in many criminal cases, but in cases within the mental and moral arena the doctor should refuse to violate the patient's confidence. He did not think that consultations between the expert witnesses on both sides would serve the ends of justice. He thought that the medical man would be much improved as a witness if a course of formal logic were part of the curriculum for a degree.

Dr. F. Temple Grey commented on the absence of uniformity in the views of the medical profession on the question of secrecy as expressed at various times, and suggested that the British Medical Association and the Medico-Legal Society should together formulate a code of conduct for the guidance of younger members of the medical profession in these matters. The view that medical confidence should be absolutely privileged was no fantastic one and was law in France. The absence of such a provision in English law might, however, be regarded as a compliment to the reticence of the profession in this country. The Hippocratic oath bound the doctor not to divulge anything that ought not to be divulged, a qualification which was often forgotten. If the law required certain evidence, then that evidence ought to be divulged, and the question was whether the law ought to be changed. He agreed with Sir William Collins that the time was ripe for some form of compromise. He proposed that disclosure should be limited to evidence of fraud, crime, and matters in which the public interest demanded disclosure. It was in the public interest that the confidence of the venereal patient should be protected as much as possible. Patients treated in venereal disease clinics should be known only by numbers.

Mr. W. McAdam Eccles exhorted expert witnesses to stick to the truth, and to appeal to the judge if the form of the question made this impossible. The "whole truth" demanded that an expert witness should be completely impartial. It was a defect of the practice of the courts that medical practitioners were regarded as all on the same plane; it should be recognised that the value of their opinions differed considerably on different subjects. Mr. McAdam Eccles was against conferences of experts, but advocated that the expert witnesses on either side should have an opportunity to confer with the medical assessor or referee. The judge, in his experience, frequently attended at such a conference.

Lieut.-Colonel C. T. Samman said he did not agree that the medical witness suffered financial loss through attendance at court.

Dr. A. Knyvett Gordon held that no pathologist should ever give evidence on the significance of any tests he made unless he had seen the patient, for the error precluded certainty.

Dr. Julius Burnford pointed to the success of the preliminary conferences which had been the rule at Leeds owing to the determination of Sir Clifford Allbutt. They had eliminated the unseemly disputes between doctors and lawyers which were common elsewhere.

The Chairman commented shortly on some of the points that had been raised.

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this Society on Feb. 12th, with Dr. H. S. Davidson, the President, in the chair, a paper on

Chronic Infection of the Cervix

was read by Dr. James Young. The condition, he said, was ten times more common in parous than nulliparous women, and the chief cause was damage of the cervix during labour. Gonorrhœa was the next most important cause. The most characteristic pathological feature of the condition was its intractableness, and this was due to the structure of the endocervix and to faulty drainage. The two most constant clinical features were leucorrhœa and pain. Menstrual irregularity and excess, bladder and bowel troubles, and general ill-health with arthritis and cardiovascular disease were also common. Dr. Young believed that chronic cervicitis was, with the possible exception of vaginal prolapse, the most common gynæcological cause of pelvic and abdominal pain. The chief site of this pain was the iliac fossa and the sacro-coccygeal region, and, as a rule, its relation to the cervix could easily be determined on vaginal examination. In health, displacement of the cervix laterally, antero-posteriorly and upwards could be produced with the vaginal fingers without inducing pain. In cervicitis fixation of the cervix was common, and any attempt at displacement immediately called forth the low abdominal or back pain. Many women suffered from nausea and, in such, retching was often caused by the same manœuvre. Dr. Young suggested that the pain was caused by irritation of the local sympathetic fibres and the somatic registering of these irritant impulses via the central nerve connexions. The iliac fossa pain of cervicitis was apt to be attributed to appendicitis or ovarian or tubal mischief. Treatment directed solely to the cervix often led to a cure of the menstrual abnormalities, and these were probably to be explained by a reflex influence on the ovaries through the sympathetic with consequent aberrant ovulation. Dr. Young discouraged vaginal douching as a treatment of cervical infection. It rarely did good, and it often did harm. Caustics and diathermy had been equally inefficacious in his hands. The lesion—dependent, as it was, on faulty drainage—could best be treated by thorough dilatation of the cervix and application of the cautery from internal to external os. Six long longitudinal smears were usually sufficient with, in addition, an individual and deep puncturing of any Nabothian follicles. The after-results showed that with a single cauterisation carried out thoroughly, cure or relief of the leucorrhœa and pain could be obtained in 70 to 80 per cent. of the cases. Relief of the other symptoms (menstrual, vesical, &c.) usually followed, and cases showing a dramatic arrest of an active and progressive arthritis were recorded.

Dr. Turner and Dr. James Davidson communicated a paper on

Symmetrical Necrosis of the Renal Cortex.

Two cases in Dr. Turner's practice were described. Both the patients were multiparæ; one, aged 37, had had four children, and the other, aged 39, had had three. Both were delivered of macerated fœti at the seventh month of pregnancy. In the first case there was an antecedent history of pre-eclamptic toxæmia and accidental hæmorrhage, but in the second no abnormality was observed during the antenatal period. Both patients lived for 12 days after delivery, and during this period the urinary secretion diminished (19 oz. in the first and 8 oz. in the second case). In both cases there was a comparative absence of growth just above the sphincter is not suitable for radium treatment on account of post-radiation discomfort. A large group of surgeons is likely to agree with these conclusions.

BOOKS FOR NURSES.

Elementary Materia Medica. Including Drugs and Solutions. By WALTER W. KRUEGER, Ph.B., Instructor, The Grand Rapids Junior College. London: W. B. Saunders Co., Ltd. 1929. Pp. 278. 8*s*.

THE output from American sources of text-books for students of nursing is an indication of the attention which the authorities are giving to the training of nurses, but the books all suffer from the same defect; they contain far more information than a nurse in training can possibly assimilate. Mr. Krueger's book is not exceptional in this respect, though in some ways it is an interesting production. In addition to the usual chapters dealing with the elementary, and for the nurse important, aspects of materia medica, such as the administration of medicines, the therapeutic classification of drugs, and the preparation of solutions, the author has introduced a chapter of general interest in the form of a sketch of the historical background of modern materia medica. He recognises also that figures may not come easily to a nurse, so he has added a simple chapter on numbers, fractions, and decimals. The book is readable and accurate. The elaborate bibliographies at the end of each chapter could quite well be dispensed with. They indicate a want of appreciation of the actual requirements of a nurse's training.

Nursing Care of Communicable Diseases. A Textbook of Prophylactic Technics for the Prevention and Control of Disease. By MARY ELIZABETH PILLSBURY, Instructor of Communicable Disease Nursing, Yale University School of Nursing. 1924–27. London: J. B. Lippincott Company. 1929. Pp. 413. 12*s*. 6*d*.

MANY nurses come to the end of their hospital training with but a scanty knowledge of communicable diseases, and in this American manual they may find a useful text-book. It is written in an interesting style and contains much information about the American public health services, stressing the duties of the nurse as a teacher of the public in matters of health. The second part of the book is devoted to the discussion in separate chapters of the various better-known infectious diseases, each disease being viewed from the medical and nursing aspects. In connexion with scarlet fever, while throat irrigation is mentioned, there is no reference to spraying of the throat, which is usually found more effective for the relief of pain both in scarlet fever and diphtheria. The book is illustrated by photographs; some of these are useful in conjunction with the description of nursing technique; the black and white attempts at reproducing the appearance of skin eruptions are not successful. Blank pages for notes are provided at the end of the book; in a later edition these might be more conveniently placed in front of the index.

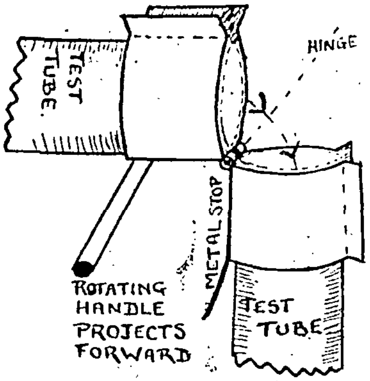
JOURNALS.

EDINBURGH MEDICAL JOURNAL.—The March issue is a special Tuberculosis Number. The first article by Dr. W. T. Munro, on Bovine-Type Tubercle Bacillus in Pulmonary Tuberculosis: Its Rôle in Pathogenesis, is annotated on p. 584.—Dr. D. Melville Dunlop writes on the Sedimentation Test in Tuberculosis, and on the Leucocytic Reaction to Tuberculosis, both in relation to their value in prognosis; and also has a third paper on the Relation between Glandular and Pulmonary Tuberculosis. In the first he comes to the conclusion we believe to be now generally accepted that the sedimentation-rate is an expression of the degree of activity of the disease, but is by no means infallible, and should never be taken alone as a prognostic index or as definite evidence of activity or inactivity. His second article on the leucocytic reaction contains the results of white cell counts from tuberculosis patients in the Southfield Sanatorium Colony. Here he notices that in health the ratio between the neutrophiles and lymphocytes is less than the ratio between the lymphocytes and monocytes. This picture is reversed in tuberculosis, and the more it deviates from the normal the worse the prognosis. In his third paper Dr. Dunlop reports that out of the last 68 cases of pulmonary tuberculosis which have been treated in the Colony, 13 have been associated with a history of disease of the cervical lymph glands, which represents a percentage of 18·9 as against 1 per cent. quoted by other authorities.—Dr. R. S. Begbie contributes a short paper on Microbic Dissociation, with special reference to Certain Acid-fast Bacilli, in which, following the lines of the work of Petroff, he has isolated rough and smooth colonies from cultures of B C G, the smegma bacillus, and Clegg's lepra bacillus.—A short note on Inoculation of Calf with Human Tubercle Bacillus, by Sir Robert Philip, Dr. J. C. Simpson, and Dr. Dunlop, records the successful production of tuberculosis in a calf by the ingestion of tubercle bacilli of human origin.—Two articles deal with social aspects of disease: one on Education of the Public in Health Matters, with special reference to the Work of the National Association for the Prevention of Tuberculosis, by Dr. William Brand; the other by Dr. A. Morrison McIntosh on Difficulties in Assessing the Capacity for Work of Ex-Sanatorium Patients.

New Inventions.

EXCRETA EXAMINATION DEVICE.

THE small device here illustrated facilitates the examination of excreta, and is inexpensive. It consists of a pair of metal clips united by a hinge. Attached to the right clip is a small metal "stop" which prevents the test-tubes touching each other. Projecting forwards from the left clip is a 10-inch rotating handle provided with a ring at end. Ordinary test-tubes are fitted into the clips. The advantages gained by this device are as follows: 1. The hands do not touch the test-tubes and so remain dry for the recording of results. 2. Burning and scalding accidents prevented when pouring. 3. Spurting when mixing is checked, the ejected fluid being received into the uppermost empty test-tube. 4. Thorough mixing of liquids the tubes may be shaken when horizontally opposed. 5. The appliance stands on the table like a tripod until reaction occurs. 6. The tubes are cleansed easily (together) under the tap and can be used singly or together. 7. The device hangs up when not in use. The makers of the appliance are Messrs. S. Murray and Co., Ltd., 11/13, Farringdon-road, London, E.C.



DAVID A. HERD, L.R.C.P., L.R.C.S. Edin.

THE LANCET.

LONDON: SATURDAY, MARCH 15, 1930.

CLINICAL RESEARCH AND EXPERIMENTAL MEDICINE.

IT will probably strike any reader of the detailed summary of the year's work given in the Report of the Medical Research Council for 1928–29,[1] or in any of its predecessors, that most of the research work supported is conducted in laboratories, and that on the whole a very small part of it has been done by men engaged in clinical medicine. The Council themselves draw attention to this circumstance, and find therein a text for an admirably clear and fair review of the relation of medical research to clinical responsibilities. Is there, they ask, a science of experimental medicine of which the actual material for study is the human patient? Or is scientific work by the physician or the surgeon limited to the application in his art of scientific results worked out elsewhere in the laboratory and delivered to him for use? Certainly there is not yet in the field of clinical medicine any stabilised or organised branch of science with a system of recruitment and promotion in the Universities. In their attempt to define the position, the Council draw a clear distinction between the work of the physician engaged in practice and the work of a man engaged in the task of advancing knowledge. The expression of this distinction evokes at first glance that sense of indignant protest which modern psychology recognises as man's natural reaction to unacknowledged and unpalatable truth. The Council state boldly that the proper performance of either of these two kinds of work tends to exclude the proper performance of the other; that the training for one is compatible with the training for the other only along part of the way. The work of a physician, and still more of a general practitioner, is devoted essentially and primarily to the task of diagnosis (not diagnosis in general, but diagnosis of the state of the particular patient), and thereafter to the treatment suitable both to the body and to the mind of that patient. The physician needs good and trained powers of observation, as well as quick, intuitive decision that only inborn aptitude and long years of experience can bring. His skill is rooted, of course, in scientific knowledge, and in his art he will make every application of the latest results of science. In the interests of his patients, however, he will be unable to make the advancement of scientific knowledge a primary object.

The research worker in the clinical field, on the other hand, must take a different point of view and follow a different discipline. He must ignore individuality, obliterate it by multiplying cases, and study the disease process as such. His thoughts must be concentrated chiefly upon the task of getting new knowledge in his chosen inquiry by every experimental method open to him, whether at the bedside or in the laboratory. It is just here that his immense difficulty lies—that of deciding what experimental methods are justifiable. In facing it the Council are less outspoken than in their appreciation of the problems of the practising clinician. They say, "Since human beings are to be the material of his study, he must learn, of course, to deal with them with the same unselfish solicitude as that of any of his brother physicians." This, it may be held, is elementary medical ethics; but situations must arise where the conduct of a collective controlled experiment in therapeutics may interfere with the welfare of an individual, and then the duty of a physician to his patients must conflict with and hamper his zeal for experimental research. Certain peculiarly able men, ingenious enough to devise questions which involve few such struggles, or fortunate in that their tastes lead them to investigations where observations made on human beings can be tested on experimental animals, are contributing notable advances to scientific medicine, in which their results are hardly less rigidly controlled than any of those recorded in laboratory work. Among them one name stands out. The Medical Research Council recall that in 1916 the appointment of Sir THOMAS LEWIS, already a physician attached to University College Hospital, to be a member of their whole-time staff, with suitable assistants, initiated the first effective hospital unit in this country. Their claim that the output of work from this centre in the scientific study of the heart and blood vascular system, its disorders and their treatment, has constituted the central stream of progress made in these subjects in any country, will be generally admitted. By contrast with this achievement some disappointment is implied, though not actually expressed, with the output of the professorial clinical units in surgery and medicine attached to the medical schools. A decade has now passed since they were inaugurated with the object of giving higher and more advanced teaching as well as organising elementary instruction in clinical subjects. They were to impart to the more able students such qualities of trained critical judgment as would fit them for the best kinds of practice, while at the same time they were to train others for an academic life of scientific clinical research. The remarkable success with which the functions of clinical teaching have been performed is here acknowledged. But these important duties, and that of taking a fair share in the administrative work of the medical schools, have tended to divert energy from other tasks and have "necessarily limited the volume of spontaneous and successful research work" coming from the units in the aggregate. Reasons of another kind are also suggested for the fact that the assistantships, whether in these university units or in the research unit under Sir THOMAS LEWIS, have not hitherto produced many men able and willing to devote themselves to a life of clinical research in experimental medicine. One is the novelty of a career in which a man is neither exactly a physician nor exactly a laboratory worker. The other and weightier factor is the absence of stable positions in which such a career may be pursued and developed with proper facilities and with reasonable remuneration. A man well trained as a clinician as well as skilled in laboratory work is thus tempted to exchange the present uncertainty of promotion and ultimate reward in scientific clinical work either for the relative certainties of professional practice, or, if he has private means or simple tastes, for an academic career in these sciences ancillary to medicine where professorial chairs are fairly numerous. These are certainly defections from the point of view of breeding whole-time clinical researchers, though for obvious reasons we should hesitate to deplore them if the succession were assured. A tendency at some of the great hospitals for the medical and surgical units to be regarded as recruiting grounds for the staff has been apparent; and this is certainly a useful way of gradually widening the scientific horizon of the honorary staff, a group whose outlook on medical problems has an incalculable influence on generations of students and therefore on British medicine. It is obvious, though, that if clinical research is to absorb a due amount of the annual grant of £150,000 placed in the hands of the Council for distribution, more men must be found who are permanently willing to devote their lives to this end. The conclusion reached by the Council is that

---

[1] London: H.M. Stationery Office. 1930. Pp. 153. 3s. An account of some of the researches carried out in the year under review will appear in a future issue of THE LANCET.

> "there can never be a successful and maintained recruitment of young men of ability for clinical research until there are at least a few stable positions in sight, the occupation of which at middle age will provide reasonable remuneration and adequate power of educating a family. It was hoped originally that the directorships of the University clinics in London, with others that might be established elsewhere in the provinces, would provide posts sufficiently numerous and attractive to keep the abler men at the work of investigation with the ambition of succeeding to them. But a young man able enough to advance knowledge is not likely to be attracted by a post to which he might be appointed in the future if his occupation of it is to bring such burdens of teaching and administration as would greatly debar him from the very research work that it is his ambition to pursue."

The Medical Research Council are trying to meet the situation by a statement of their intention to encourage still further the scientific and direct study of disease in man. They wish to recruit for this purpose young workers of ability, to help them during a preliminary period of training and probationary work, and, when they are able, to select candidates whose training is adequate and whose efforts show promise to increase the number of clinical workers on their permanent staff.

We are impressed with the arguments in this carefully worded section of the Council's introduction to a masterly Report. No hint is given of the type of training to be offered, but doubtless this will follow the time-honoured lines of apprenticeship to one with knowledge of the difficulties involved, or association with a team of workers. Whatever form the discipline takes, it is to be hoped that an elementary grounding of statistics as applied to medicine will be imperative. Where the material available for study is so precious, and sometimes so difficult to come by, it is unjustifiable to waste it by planning work which, examined statistically, is of little value compared with the controlled observations that might have been made. Criticisms offered, and legitimately offered, on the outcome of laborious work which has extended over years are sometimes resented. It is pardonable to be disheartened if figures honestly collected are found to be meaningless, but not to condemn statisticians for exposing fallacies due to ignorance of proper methods. Where many unknown factors can be eliminated, as in a well-constructed laboratory experiment, the need is perhaps not so great; but the assessment of clinical research, to be economical, requires either great experience, natural ability, or some knowledge of the laws of probability and averages. A significant sentence in the section on Statistics (p. 123 of the Report) reads, "Much time and energy have again been used in giving statistical help to research workers in other departments." It is unlikely that a brief training in applied mathematics would make it possible to dispense with the assistance available from Prof. MAJOR GREENWOOD and his staff, but it might at least enable them to economise some of the "time and energy" so generously offered to other workers.

◆

ÆTIOLOGY OF DISSEMINATED SCLEROSIS.

DISSEMINATED sclerosis is one of the commonest chronic diseases of the nervous system. In England it ranks second only to neurosyphilis in frequency; in Switzerland it holds the foremost place. But in spite of its prevalence its cause has hitherto remained in doubt. Until the present century even its pathological nature was much disputed. Histological study, however, tracing the "sclerotic plaque" to its earliest stages, has there discovered all the manifestations of inflammation in the nervous system, and increasing knowledge of neuroglia has led to the recognition of the glial "sclerosis" as an inflammatory reaction rather than a neoplastic hyperplasia. Hence disseminated sclerosis is now almost universally regarded as an encephalomyelitis characterised histologically by neuronal demyelination and clinically by its relapsing tendency. This conception has naturally led to the search for a causal organism, and to many conflicting observations. Some workers have claimed to have transmitted a neurotropic virus of unknown nature from cases of disseminated sclerosis to animals. Others have impugned a spirochæte. Many completely negative experimental observations have been recorded, and no positive claim has gained general acceptance. To-day we publish a paper by Miss KATHLEEN CHEVASSUT, bringing forward evidence in favour of the view that the cause of disseminated sclerosis is a filtrable virus which she claims to have isolated from the cerebro-spinal fluid of a large number of patients. This discovery, if it is substantiated, will certainly rank among the foremost achievements of bacteriology. Other bacteriologists will doubtless avail themselves of the opportunity of repeating Miss CHEVASSUT'S experiments. This, however, must take time. In the meantime it is desirable that her claim should be subjected to all possible well-informed and fair-minded criticism, and that hasty acceptance and rejection should equally be avoided.

Miss CHEVASSUT first describes some original observations upon the colloidal gold reaction in the cerebro-spinal fluid and blood-serum in disseminated sclerosis which she interprets as indicating that this reaction "is related in some way to the causal factor." She then brings forward evidence that "in a high percentage of cases of disseminated sclerosis there is deficiency in the antitoxic and metabolic functions of the liver." Both of these conclusions are open to criticism, but they have no direct bearing upon her main thesis. She reports that in a special medium, Hartley's broth to which human blood-serum has been added, she has succeeded in growing an organism which, when examined microscopically by a special technique, appears as spherical bodies, some of which have granules attached to them. She has cultivated this organism from the cerebro-spinal fluid of 176 out of 188 cases of disseminated sclerosis, and has found it present in all stages of the disease. She describes the conditions affecting its growth and has observed that it ferments glucose, lævulose, and mannite

The granules have been shown to pass through collodion membranes. These positive observations have been controlled by culturing the cerebro-spinal fluid from 269 persons suffering from other conditions, always with negative results. Miss Chevassut, then, appears to have demonstrated the presence of certain bodies in cultures made from the cerebro-spinal fluid of patients with disseminated sclerosis. Is she entitled to conclude that these bodies constitute the causal organism of the disease? We must now consider how this conclusion might be criticised, not necessarily as incorrect, but as requiring further evidence before it can be regarded as proved. The bodies have never been demonstrated in the cerebro-spinal fluid itself. There may be good technical reasons for this, as Miss Chevassut suggests, but if these difficulties could be overcome it would go far to remove the possibility that the supposed organisms may be products of the interaction of the fluid and the culture medium. It may be strange to regard the uniformity of the success of an experiment as evidence against its validity, but workers with the filtrable viruses may be inclined to regard the demonstration of the virus in 93 per cent. of the specimens examined as almost too good to be true, especially when the material is derived from quiescent as well as from active cases. It may be suggested that some bio-chemical change in the fluid is more likely to be thus constant than the presence of the organism. It seems desirable, too, that some attempt should be made to ascertain whether the virus is obtainable from nervous tissue as well as from cerebro-spinal fluid. It is naturally the aim of all who claim to have isolated an organism to transmit it to animals, to show that in inoculated animals it produces the symptoms and histological changes of the disease in man, and that it can be recovered and cultivated from animals thus infected. The evidence that these tests have been successfully carried out with Miss Chevassut's organism is at present inconclusive.

Sir James Purves-Stewart, in the paper on p. 560, summarises experiments which he has carried out in conjunction with Dr. Braxton Hicks and Dr. F. D. M. Hocking, and which will be fully reported in our next issue. It is disappointing that more striking results were not obtained from such drastic inoculations as the intravenous and intracisternal injections of cultures of the virus into monkeys. Possibly the monkey is not a susceptible animal, though G. Steiner has described the successful inoculation of a monkey with the disease. Perhaps intracerebral inoculation would yield better results. There is nothing in Miss Chevassut's observations inconsistent with her view that she has isolated the organism of disseminated sclerosis, but the proof of her contention can hardly as yet be regarded as complete. We sincerely hope that further investigations will prove her right, and neither she nor Sir James has spared pains in their admirable work.

We turn now to the practical applications of the observations we have been discussing. An exceedingly important one is entirely independent of their interpretation and, curiously, has not been mentioned either by Miss Chevassut or by Sir James Purves-Stewart. Whether or not the *Spherula insularis* is the cause of the disease, if the existence of these bodies is confirmed their diagnostic value is clearly very great. A test applicable to the cerebro-spinal fluid which yields a positive result in 93 per cent. of cases and is pathognomonic of disseminated sclerosis, will be an even more valuable aid to the diagnosis of this disease than is the Wassermann reaction in neurosyphilis. It will be of great use in early cases, and also may be expected to throw light upon the relationship between disseminated sclerosis, neuromyelitis optica, and other forms of demyelinating encephalitis. The isolation of a causative organism suggests the therapeutic employment of an autogenous vaccine, and Sir James Purves-Stewart contributes a weighty paper setting forth the results achieved by means of killed cultures of Miss Chevassut's organism. He wisely emphasises the need of caution in drawing conclusions as to the effects of any therapeutic measure in disseminated sclerosis. His patients have apparently only been under treatment for one or two years, a time too short to permit one to speak with confidence of clinical arrest. The clinical improvement which occurred in the four cases fully reported is not greater than may occur spontaneously. Sir James Purves-Stewart lays stress upon improvement in the colloidal gold and globulin reactions in the cerebro-spinal fluid. The significance of these changes could have been better appreciated if controls had been investigated. J. D. Ayer and H. E. Foster have observed spontaneous variations in the colloidal gold-curve corresponding to progressive and stationary phases of the disease, and Adams, Blacklock, Dunlop, and Scott have found a diminution in the curve following treatment with salvarsan. The disappointing feature of the vaccine treatment is the fact that after treatment the organism was still obtainable from the fluid in 62 out of 70 cases. This fact, of course, has no direct bearing upon the question of the specificity of the organism. The discovery of the tubercle bacillus and the *Treponema pallidum* has not led to the cure of tuberculosis and syphilis by means of vaccines. Disseminated sclerosis, another relapsing disease, seems to offer a rather unpromising field for such treatment, for natural immunity, at least, appears to be short-lived.

Miss Chevassut, Sir James Purves-Stewart, and their collaborators have laid before the medical profession observations of great interest, involving matters of technical difficulty in more than one department of science. The work required for their confirmation must necessarily take many months. In the meantime, the wise (among whom we may include the lay press) will suspend judgment.

HEALTH AND EMPIRE.

The Hastings Lecture delivered by Sir Andrew Balfour in the Hall of the British Medical Association last Wednesday, a brief abstract of which will be found in our front pages to-day, is an eloquent plea for the development of medical research, with the development of the British Empire as the source of the information given and of the arguments set out. He paints a picture of a great battle between man and disease as witnessed in the various phases of the expansion of British rule. The story of tropical disease to-day is sufficiently tragic, but the ravages of endemic, epidemic, and incidental disease which occur within our borders in the twentieth century represent but a small fraction of the horrors which in the previous epochs decided the fates of armies and navies, and slew, or harassed to the point of death, the pioneers of colonial expansion. And when we speak of previous epochs it should be recalled that many of the diseases, now labelled tropical, until the middle of the nineteenth century flourished in our midst. Sir Andrew Balfour reminded his hearers that as late as 1866 cholera was present in England and that three years later relapsing fever was claiming victims in the poorer parts of London. As a matter of fact, at Somerset House deaths were registered from this cause over England for the next thirty years, though it is probable that there was here sometimes a confusion between relapsing fever and other forms of infantile fever. Malaria may be considered as absent now from the home shores, but the part played by ague in the country practitioner's responsibilities finds record up to mid-Victorian days.

Truly we have but just passed from the shadow of these diseases, and a pertinent lesson to be derived from the Hastings Lecture is that it was an apathy bred of ignorance which left us, in common with the rest of the world, so long their prey. Are we learning our lesson? Some two generations have now gone by since the establishment of compulsory education in this country, and with the disappearance of the illiterate it has become possible to diffuse general ideas of sanitation and general instructions for the preservation of health to a population who can follow the teaching. And during the last 15 years a remarkable impulse to the propagation of such teaching has been given by the experiences derived from the recent war. Those who expected that a newly educated public would at once become docile and receptive of wise teaching must have been sanguine, for the first result of popular education was the creation of a large class whose equipment just encouraged them to criticise what they did not understand, while it provided them with no opportunities and no incentives for pursuing their studies in such a way as to render their imperfect knowledge of greater use to the community, or of more solid comfort to themselves. That at any rate was the position which, until lately, the bulk of the population occupied in respect of medical science and medical endeavour. The nineteenth century may have been slow to organise the national fight against disease, but until recently the public conscience has not been roused by medical warnings. Now on all sides there are signs that the general public is awakening to the fact that in its own hands lies much of the power to prevent disease, to limit its spread, and to alleviate its miseries. The significance of their freedom from much of the sufferings of their parents and grandparents is perceived. At home we are reaching a stage when real coöperation between medicine and the public is taking place, but much time must elapse before such a state of affairs can be expected in many vast tracts of the Empire where tropical diseases are rife. What might be achieved by the education of the native in elementary hygiene was set forth persuasively by Prof. B. BLACKLOCK in a recent Chadwick public lecture. For the present reliance must be placed largely upon the efforts of experts, and for the training of these the London School of Hygiene and Tropical Medicine, whose activities Sir ANDREW BALFOUR directs, is the great new centre.

Research is the weapon which, wisely yielded, can open up for us paths in the jungle of ignorance, dispelling darkness and gloom and revealing vistas of hope and cheerfulness, health, and longevity. The Hastings Lecture demonstrated how good an ally to health the British Empire had been as a civilising and colonising power. With pride in our vast possessions, however, we must own to world responsibilities. We possess unique and often tragic opportunities of becoming intimately acquainted with tropical disease, and it becomes to us a national duty not only to alleviate and where possible remove the burdens of sickness in the interests of our own citizens, but to collect and sift the evidence by which the world may benefit.

THE REGISTRATION OF INDIAN MEDICAL DEGREES.

THE long and patient negotiations between the Government of India and the General Medical Council, in respect of the recognition by the Council of Indian medical degrees, have, at any rate for the time being, broken down. Since 1922 the Council has been striving to secure the registration of Indian graduates on a plan which will guarantee that their place is due to the possession of a professional training up to the standard required for practice in Great Britain and Ireland. The story, therefore, is a long one, but to detail its closing phases will be sufficient to make the situation clear.

At the meeting of the General Medical Council last November the President pointed out that the period for which the recognition of Indian medical degrees for registration in Great Britain and Ireland had been provisionally guaranteed was fast running out, while the appointment of a Government Commissioner of Medical Qualifications and Standards had not been made. The appointment of this officer was itself a provisional measure designed to furnish the Council with a responsible nominee, whose reports they could accept, until the promised institution of an All-India Medical Council came into material being. Apparently it was hoped by the Indian Government that the appointment of separate inspectors ad hoc would be accepted by the General Medical Council as a substitute for the Government Commissioner, but the reports of these inspectors which had been received were found to contain no reference to any common standards comparable with those which hold good in this country, while they disclosed individual deficiencies in regard to Indian methods of training and testing which could not be overlooked. To put it briefly, the position was that the General Medical Council, though furnished with these ad hoc reports, remained without evidence that the requisites, demanded by the Medical Act of 1886 before legal practice in Great Britain and Ireland can be undertaken, would be forthcoming. The Government of India, although informed of this, and repeatedly warned that the existing position could not continue, remained inactive. The appointment of a Government Commissioner of Medical Qualifications and Standards was not made, although the Council said plainly that registration for practice in this country of the medical graduates of certain Indian universities must otherwise cease early this year. Then, at the beginning of this year, a letter was received from the India Office saying that the appointment of the Commissioner was not possible, but stating that the Government of India proposed to proceed with the appointment of a Board to discharge the duties of the All-India Medical Council until that body came into existence. This Board, the India Office stated, would consist of the Director-General, I.M.S., and representatives of the medical faculties of the Indian Universities, and one of its duties would be to appoint certain inspectors as intermediaries between the Board and the General Medical Council. The Council, in the meantime, had received telegrams from the Viceroy stating that the appointment of the Commissioner was not possible, but putting forward a recommendation, received from a conference of the Indian Universities that, pending the creation of an All-India Medical Council, a Board consisting of representatives of the Government of India and the medical faculties of the Universities should be appointed as a temporary measure. A further telegram from the Viceroy indicated that this Board, being established, would appoint inspectors, specialists severally in medicine, surgery, and midwifery, to report on the standards of Indian medical education and examinations, thus guaranteeing to the Medical Council that the possession of the medical degrees of a particular Indian University "ensured possession of the minimum qualifications accepted for registration in Great Britain."

This was the situation to be considered at a meeting of the Executive Committee of the General Medical Council on Feb. 24th, when it was felt that the perpetuation of temporary remedies for the main difficulty—namely, the possible registration of persons below the legal standard—was inadvisable. For not only had this country to be thought of, but all the overseas dominions. With these reciprocity is earnestly desired, but they will take no steps to such an end if doubts are raised about the standards demanded by the General Medical Council. It was accordingly resolved :—

(*a*) That, in the absence of authoritative information respecting the medical qualifications and standards of the Indian Universities of Bombay, Calcutta, Lucknow, Madras, and Punjab, the Executive Committee of the Council, in fulfilment of its duty under the Medical Act, 1886, Section 13, is unable for the time being to recognise the medical degrees of these Universities as "furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery" in this country; and that accordingly the conditional recognition hitherto granted to these degrees has now lapsed.

(*b*) That the proposal by the Government of India to appoint a temporary Board, contained in the letter from the India Office of Jan. 11th, 1930, has been carefully considered by the Executive Committee; but it is unable to accept the proposal as furnishing a satisfactory method of supplying the Council with authoritative information on medical qualifications and standards in India, and with the necessary guarantees of sufficiency.

A third resolution dealt in similar *non possumus* way with the situation at the Universities of Rangoon and Patna, whose degrees have never been recognised. All who have followed the various negotiations step by step will be prepared for the Council's decision. The Council has displayed patience and tact in the prolonged discussions, has taken evidence upon the spot before forming its conclusions, and has formed them only when the lapse of time made action necessary. Upon an important section of Indian students the veto against registration in this country will bear hardly, and especially will their teachers and the authorities of the Indian Universities be unwilling to admit that further delay could not be granted. But those who realise the necessity of keeping medical practice in this country up to an adequate level of efficiency will see that the course taken by the Council is right.

◆

THE Red Cross Clinic for Rheumatism will be available for treatment on Monday next, and applications for appointments may now be made either by letter addressed to the Medical Superintendent, Peto-place, Marylebone-road, London, N.W.1, or telephone Museum 9441. Representatives of approved and friendly societies, trade-unions, and others interested in the treatment of rheumatism are invited to visit the Clinic and inspect the building and its equipment.

REST ROOMS AT ST. BARTHOLOMEW'S HOSPITAL.—Rest rooms for relatives and friends of patients in St. Bartholomew's Hospital are being provided, at a cost of £15,000, by the butchers of Smithfield. The rooms, which include lounges, a canteen and cubicles, are now approaching completion and are expected to be ready for use a few weeks hence. The money is to be provided by the deduction of 10 per cent. from the total subscriptions to the Derby sweepstake of the Smithfield Mutual Benevolent Fund.

Annotations.

"Ne quid nimis."

CHILD PSYCHOLOGY.

WHAT is it that has led in recent years to the sudden and passionate interest in the child's mind, to a curiosity in discovering not only the lines of its normal development, but the reasons for its strange divergences? Perhaps we are at the end of an epoch in which all our growing mechanical devices are leading us away from the world of nature into one of mechanism, against which however life itself is still strong enough to put up a fight against all processes making for petrifaction. It is not surprising therefore that we should be endeavouring to safeguard the tender plant, the child, while still green and pliable and capable of taking such shape as we think best for its own happiness and for the good of the community. The study of the child has been to many the ground of normal psychology; to others it has been a study for its own sake; to many modern students the study of the child for its own sake is a prelude to understanding the disorders of the child mind which make even for physical disability as well as for anomalies of behaviour. Understanding of these disorders, as Freud and his school have shown us, is a prelude to understanding the disorders of the adult mind. There has been so much written on abnormal psychology of the child in the light of psycho-analysis that students may forget, even if they have at one time been aware of, the contribution made to this subject by those who have made researches in the normal field. We have to be thankful particularly to two pioneers in human psychic origins as manifest in the study of the child mind, Jean Piaget and K. Koffka. In a revised edition[1] Prof. Koffka has given us an acute analysis of the mind of the child from a unique angle, an angle which has illuminated academic psychology as it has not been illuminated for more than a quarter of a century. The study of mental processes as configurations (*Gestalten*) has to many freed psychology from an atomism which enslaved it for many years. It is a psychology which has to recommend it a conformity with the recent researches of Lashly and, more remotely, with Head's conception of aphasia. In Prof. Piaget, whose works continue to be translated and are accessible to all, we witness the production of a new method by questionaire for throwing a light on the mental processes of young children in order to determine the way in which their world is built, the form and function of its conception of the external wold. In his recent volume[2] Piaget gives us the fascinating immediate material for understanding the strange animism and idea of participation which underlies the realism of the child. He analyses the child's attitude towards the objects and forces of nature, and to those who can view his discoveries in the light of the dynamic psychology of Freud, a new vista will be opened up into the recesses of the child's mind. For those who have once entered this Aladdin's cave of child wonder and have studied the transformation from infancy to adolescence, there will be no going back. To guide the new Child Guidance Movement these volumes will be invaluable. The same may be said of a study by Dr. James Drever and Dr. Margaret Drummond.[3] Here, too, we have an analysis of the child mind from the periods of pure instinctual movement and satisfaction to the nursery school. It is, in many ways, a practical expression of the foregoing works, although it does not actually deal with either the methods or problems of Koffka and Piaget.

PULMONARY TUBERCLE OF BOVINE TYPE.

THE occurrence of the bovine tubercle bacillus in pulmonary infection has hitherto been considered a rare curiosity of little practical significance. For example, Park and Krumweide, in the United States, only record two instances of undoubted bovine infection in 680 cases of pulmonary tuberculosis, whilst A. S. Griffith, in this country, has found three instances in 212 cases. But Dr. W. T. Munro, of the Fife and Kinross Sanatorium, Glenlomond, has re-examined the matter in the light of a large series of experiments on sputum and pus from cases occurring at the sanatorium, using as his standard of identification of the bovine type its dysgonic growth in culture and its low virulence on intravenous inoculation in rabbits. Details of the viruses are given in a paper which appears in a special Tuberculosis Number of the *Edinburgh Medical Journal* (March, 1930, p. 141). Two years ago in our own columns [1] Dr. Munro gave an account of five cases from whose sputum tubercle bacilli of bovine type had been grown in culture. He has now double this number, ten of bovine type out of 250 cases. In four of these the disease had spread from the root of the lung, five showed the distribution common in pulmonary tuberculosis of human type, and one stood alone with multiple abscesses. Setting this case aside, Dr. Munro notes as the most striking features of the series (1) the amount of fibrotic change, (2) the lack of evidence of much breaking-down of lung tissue, and (3) the absence of hæmoptysis. Although he does not wish to overstress these points he does suggest that there is more chance of bovine tubercle patients overcoming their systemic disturbance than would be the case with a similar group of infection with human type. Dr. Munro then asks certain pertinent questions and endeavours himself to supply answers to them. Why, for instance, are bovine-type tubercle bacilli so rarely found in the sputum of patients suffering from pulmonary tuberculosis? The bovine bacillus being dysgonic it is, of course, more likely to escape attention by those bacteriologists who cultivate and investigate the tubercle bacillus in sputum, and, according to Dr. Munro, it is just when tubercle bacilli are scanty that there is most chance of their being bovine. He is inclined to think that his higher percentage of positive bovine is due to the fact that he has made cultures from every sputum in which tubercle bacilli were present, whether numerous or scanty. Again, he asks, is the bovine virus less capable of generalisation in the human subject than the human virus? Dr. Munro quotes evidence to show that there is a larger percentage of recoveries in bovine-type infections, and he believes it to be a reasonable argument to advance that the bovine type is not so capable of general lymphatic spread in the human subject as is the human type. Referring to Marfan's law of the rarity of pulmonary tuberculosis in persons who during childhood have had suppurative adenitis of the neck, Dr. Munro states that in cases where he has had the opportunity of examining material from both cervical gland and sputum in the same patient he has always obtained the human-type bacillus. Furthermore, tubercle bacilli from kidney lesions are in the experience of most workers almost always of the human type. Going on to consider Aschoff's division of pulmonary tuberculosis into two types, exudative and proliferative, Dr. Munro suggests that the allergic response to the bovine bacillus is more likely to be of the proliferative than of the exudative type, and thinks that when tubercle bacilli are found at the beginning of the illness with a bovine infection they are likely soon to disappear because of this proliferative response. This benign bovine infection may lead to protection against superinfection by the bovine type, while it is apt to break down when confronted with the human type of bacillus. Finally, he asks, is it possible that the bovine disease has been contracted by aerogenous infection? In none of the cases was there any family history of tuberculosis, and in only two was there any account of contact with cattle on farms in earlier years. Dr. Munro remarks: "But when one stops to think of these ten cases of pulmonary tuberculosis due to bovine-type tubercle bacilli, one must accept that it is most unlikely that superinfection was air-borne. And if these cases are not air-borne, is chronic pulmonary tuberculosis ever air-borne?" Subcutaneous inoculation on animals has satisfied him that, contrary to the usual experience, it was possible to produce chronic pulmonary tuberculosis with cavity formation. Experimentally, then, it is not essential for the tubercle bacillus to be air-borne in order to produce chronic disease of the lung.

THE ÆTIOLOGY OF PSORIASIS.

DETERMINED efforts to ascertain the cause of psoriasis have been made. Two main theories are held, the metabolic and the parasitic, the former of which includes the endocrine and neuropathic. A great deal of research, with which the name of Prof. Schamberg of Philadelphia is particularly associated, has been expended on the biochemical side of the problem, but no positive conclusions have been reached. A group of American dermatologists have recently published [1] the results of exhaustive mycological studies concerned with the relatively common occurrence of monilia, a yeast-like fungus of increasing importance in dermatology, in the psoriatic lesions, the fæces, and the blood of patients affected with the disease. The authors make no extravagant claims, but their work has obviously been most carefully done, and nothing has been omitted or over-emphasised with a view to converting readers to the importance of the findings. It was first ascertained that in 100 stools of persons without psoriasis the monilia in question could be recovered in six. In patients with gastro-intestinal disturbance the percentage rose to 40. Normal persons do not harbour the organism on the skin of the elbow (26 cases examined), nor is it a common superinfection in conditions such as eczema, although Castellani and others have isolated it from various lesions, mostly of intertriginous type, in the groins, perineum, and interdigital spaces.

Wachowiak and Fleisher have demonstrated monilia organisms in the blood of certain cases of sprue and other intestinal infections. They state that its significance is not entirely clear, but in view of the fact that ringworm organisms are occasionally present in the circulation in cases of kerion type of tinea, the possibility of a direct connexion between the organism and the disease deserves consideration. Their investigations in cases of psoriasis show that in the first series of 24 persons monilia was found in the fæces in 20, in the blood in 5, and in the skin scrapings in 11. In their second group of 32 patients the organism was isolated from the fæces of 30, from the blood of 3, and from the skin of 9. Skin susceptibility tests with the organism were carried out with due controls and independently by Prof. Strickler, whose results certainly support a specific allergy in affected persons. In 40 cases 31 showed a "strongly positive reaction," and in all the other 9 there was "an evident reaction." Animal tests and attempts to reproduce the disease both in them and in man were unsuccessful. It is clear that Koch's postulates are not fulfilled, and the causal relationship of monilia and psoriasis is certainly not proved, but the connexion is sufficiently striking to warrant further investigation. Another method of study was attempted with only partial success. Cultures of monilia were sterilised and injected into a psoriasis patient in appropriate vaccinal doses. A few cases cleared up for a time, but the majority either showed no result or relapsed, in just the same way as these patients are apt to do after any protein injection. The authors themselves have little doubt that monilia is in some way related to psoriasis. They remind us that it is the undoubted cause of thrush, and has been claimed as the cause of sprue, some cases of bronchitis and pneumonia, and erosio interdigitalis and epidermycosis. That this organism can function as a pathological agent in the production of diseases is not disputed; but here, as elsewhere, the presence of monilia may be only of secondary significance. Medicine teems with examples of such symbiotic relationships. It is generally acknowledged that many of the symptoms of pulmonary tuberculosis are due to streptococci and staphylococci, and that the majority of fatal cases of malignant disease eventually die of sepsis. It is possible that the relatively poor reactive powers, which it is safe to assume for the psoriatic lesion itself, is the probable cause of the relative abundance of monilia organisms to be found there, and also the indirect cause of the invasion of the blood stream by the organism and of its excretion in the fæces.

[1] American Archives of Dermat. and Syph., 1929, xix., 713.

It is surprising that in setting out their conclusions the authors have not discussed the possibility of such a mechanism. Their paper, however, is worthy of consideration as a serious contribution to dermatological research.

THE DRAFT POOR LAW ORDER.

A FEW years ago the Minister of Health found it impossible to proceed with the reform of the poor-law until the relevant existing statutes had been written out in intelligible form. The result was the consolidating Poor Law Act of 1927 which, though it preserved many provisions which were about to undergo drastic reform, offered the reformer a reasonable chance of reconnoitring the ground he was to attack. Something of the same sort seems to be happening to the Minister's poor-law Orders. The tangle of the present Orders has still some strands of a code issued as long ago as 1847. The Minister has produced a new draft Poor Law Order in nine parts, re-writing the previous provisions under such heads as Institutions, Hospitals, Children's Homes, Boarding-out of Children, Apprenticeship, Casual Poor, and Officers and Servants. His draft is expressly stated to be a consolidation of the existing orders with adaptations consequent upon the passing of the Local Government Act of last year. This means that, as that Act abolishes boards of guardians and substitutes the councils of counties and county boroughs, the nomenclature of the poor-law orders is in this and other respects brought up to date in the light of the table of equivalents contained in Schedule 10 of the Act. Other changes have, of course, to be made. References to the overseers disappear because those officials were abolished by the Rating Act of 1925; and the central authority which in 1847 was set up as the Poor Law Board and which in 1871 became the Local Government Board, now the Ministry of Health, must naturally be referred to by its modern title. On the other hand poor relief has not yet been replaced by the new label "public assistance."

The draft Poor Law Order, therefore, it seems, is a mere modernisation of outstanding provisions, a necessary preliminary to any fresh developments. The draftsman appears to have done his work neatly and concisely. The three-page "Paupers Conveyance (Expenses) Order" of 1898, for example, seems to have been reduced to seven lines in Article 19 of the draft, while the 17 pages of the "Boarding-out Order" of 1911 seem to be contained within the four pages of Part VI. of the draft. There is only one complaint to make. Article 7 of the new code says airily that all rules, Orders, and regulations, whether general or special, heretofore made by the Minister under the law in force from time to time relating to the relief of the poor, so far as not already rescinded, are hereby rescinded (except certain sets of orders and regulations which are expressly saved). This is a slovenly method of legislation, unfair to the public and exasperating to anyone who honestly tries to find out the law. The draftsman knows perfectly well which Orders he is superseding and reproducing in his new document. Why does he not set them out in a list and remove uncertainty by definitely revoking each one?

The draft Order, it will have been understood, seems to involve no change in the law. No medical officer of health or medical practitioner will find himself any the worse. Everyone, in fact, must welcome the clearer and more concise statement on a subject which is so rapidly changing. Already the consolidating Poor Law Act of 1927 is to be replaced by a fresh consolidating Act which has passed through Parliament. It remains nothing less than a scandal that the same process is not applied to the general law of public health and local government based on statutes passed half a century ago. The law is uncertain as well as out of date. Anyone who tries to search out the powers of county borough councils, for instance, has a dismal task ahead of him. It is not well that a department should be the only repository of knowledge in these matters. Let the Ministry of Health carry the process of consolidation further.

ŒSOPHAGEAL OBSTRUCTION IN CHILDREN.

AN anatomical or physiological defect of the œsophagus, serious as it is at all ages, is doubly so in childhood, when it threatens the efficient performance of the functions needed for growth and development, as well as for maintenance of bodily health. Except in such conditions as atresia and congenital stricture, it has long been recognised that there is a possibility of recovery under prolonged and careful treatment, but there has been considerable divergence of opinion on the mode of treatment yielding the best results. It seems likely that the conflicting evidence on this point has been to some extent due to an imperfect classification of the defects encountered, and that a clearer conception of the pathology of these cases will divide them into diverse types, for each of which a different therapeutic technique is indicated.

The work which has been done by J. A. M. Cameron, G. W. Raike, and others has shown that the condition of cardiospasm, or achalasia, is a definite clinical entity dependent on a defect of neuromuscular mechanism, associated with degeneration of Auerbach's plexus in the lower end of the œsophagus. Good results have been obtained in this disorder by the passage of mercury bougies, continued over a long period, as described by A. F. Hurst.[1] The treatment of œsophageal obstruction has, however, been decidedly less satisfactory in small children than in older ones and in adults. A valuable communication by Dr. Wilfrid Sheldon and Dr. A. G. Ogilvie[2] strongly suggests that this may be due to the fact that the obstruction in children is usually occasioned by some factor other than achalasia. These authors have made a careful study of six children observed by them at the Hospital for Sick Children, Great Ormond-street, and of the records of six cases previously treated there. Of these 12 cases, two only showed obstruction at the level of the diaphragm, and they appeared to be cases of congenital stricture. In the remaining ten the obstruction was at the level of the seventh thoracic vertebra, and they appear to form a clinical group with well-defined characteristics. In all the severe cases the vomiting dated from birth or the first few weeks of life; it usually became more severe when solid food was added to the diet. It was possible to observe some of these children at intervals during a number of years, and to compare the radiographic appearances at different ages. The authors are of the opinion that these children did not obtain real benefit from the passage of bougies. In the case-histories of some of them immediate improvement is recorded as following this measure, but it was usually followed by re-admission with recurrence of the symptoms, sometimes in an aggravated form; in no case was a lasting benefit or a cure obtained. The cases in which the greatest improvement—sometimes amounting to cure—was obtained were those which were treated by prolonged restriction to a fluid diet, without the passage of bougies. Only two of these came to autopsy; in one of them the symptoms had been cured at the age of 3½, and death from tuberculosis occurred later, the œsophagus being found to be absolutely normal.

---

[1] THE LANCET, 1927, i., 618.

[2] Arch. Dis. Child., 1929, iv., 347.

Sheldon and Ogilvie make some interesting suggestions on the pathology of this type of œsophageal obstruction. They believe that the abnormality is congenital. This conception is supported by a high incidence in premature children and a four-to-one ratio of males to females, as well as by the onset of the symptoms in early infancy. They suggest that a narrowing may take place at the junction of the two segments (retropharyngeal and pre-gastric) of the foregut by the union of which the œsophagus is developed, or that the lower segment may be narrowed as the result of inadequate growth. If suitable conditions can be maintained—the most important being a purely fluid diet—spontaneous cure of the symptoms may be achieved by the growth of the œsophagus to a calibre adequate for the transmission of solids. They have certainly made out a case for regarding the majority of œsophageal defects in children as something different from achalasia, and for giving prolonged trial to this method of treatment.

LIVER IN ANÆMIA.

WITHIN the last four years a great deal has been added to our knowledge of the use of liver in the treatment of anæmia, and Dr. Janet Vaughan[1] finds a general consensus of opinion that it is a certain remedy for those forms associated with a megaloblastic hyperplasia of the bone-marrow. The best known of these is, of course, "pernicious" anæmia, but a good deal of evidence has now accumulated tending to bring under this heading the *anæmia of* sprue and also the type described by Channing, in the 'forties of last century, as the "grave anæmia of pregnancy." It has still to be directly proved whether there is megaloblastic hyperplasia of the bone-marrow in this last type of anæmia, but the condition is characteristically associated with a high colour-index, and this is indirect evidence of such hyperplasia. In all these states there are signs that the therapeutic action of liver is seriously inhibited by sepsis, but this is not to be taken as an indication that sepsis is in any way their cause. It is further generally agreed, says Dr. Vaughan, that liver is useful in the treatment of anæmia secondary to gastric and other hæmorrhage, and that in these conditions its action is enhanced by simultaneous administration of iron. It is also of value in certain of the nutritional anæmias. Whether the principle effective in anæmia of the megaloblastic type is the same as in the others remains uncertain. There is little doubt that in the megaloblastic forms the effective principle is the polypeptide isolated by E. J. Cohn; in the secondary anæmias the inorganic salt content of the liver may be of importance, and this may explain the observation that liver extracts are useless in certain types of anæmia, particularly those with a nutritional basis, which respond well to whole liver. On the evidence to date Dr. Vaughan comes to the conclusion that pernicious anæmia must be regarded as a deficiency disease, having as its basis the absence of some principle normally present in both liver and kidney, without which the bone-marrow cannot produce or liberate its normal quota of red cells. As to the mode of action of the liver, two different views are held. J. Müller believes that pernicious anæmia is due to over-action of the reticulo-endothelial system, resulting in the production of megalocytes at the expense of normal red cells; he thinks that liver acts by inhibiting the megalocytic hyperplasia and giving an opportunity for formation of normal red cells. G. R. Minot believes that the primary deficiency is failure of the red cells to attain maturity and that liver acts by stimulating the cells to complete their growth cycle. His view gains much support from embryology, and bids fair to be established. But even so, the nature of the force causing this abnormality in the growth of the red cells remains obscure.

CLINICAL EFFECTS OF OVARIAN HORMONE.

IN a preliminary communication to the Royal Society of Medicine (Section of Therapeutics and Pharmacology), on Tuesday last, Prof. E. C. Dodds and Dr. J. D. Robertson put the landmark in the history of ovarian hormone research at the time when Allen and Doisy first standardised the material by the vaginal smear method. Characteristic cells appear in the smear during the three stages in the cyclical changes, and Allen and Doisy showed that the injection of extracts made with the use of volatile solvents would cause these changes to reappear. As there is a definite quantitative relationship between the amount of hormone injected and the changes in the vaginal smear the biochemist is now able to estimate the strength of his preparations. This has enabled him to proceed with the purification of the material so that whereas in former years the preparations were in the form of a stiff oil, insoluble in water and with a rat-unit of only 10–15 mg., nowadays it is possible to obtain a water-soluble material containing several hundred rat-units to the milligramme. In this form it can be injected into human beings without causing any of the severe local and general reactions that it produced in the past. When injected subcutaneously œstrin has been known to produce: (1) œstrus in ovariectomised animals, (2) premature puberty in young immature female animals, and (3) abortion of pregnant animals. It does not follow, however, that it will therefore cause menstruation and abortion in women, and it is not fair to expect it to induce processes in human beings which possibly bear only a distant biological relationship to those occurring in the lower animals.

The preparation employed in the clinical experiments related by Prof. Dodds and Dr. Robertson was made by the process already published from the Courtauld Institute of Biochemistry and contained 10 rat-units per c.cm. Since the investigators were quite in the dark on the dosage all the patients received 1 c.cm. per day for two months. It was thought that the best results would be obtained by giving a series of small doses over a considerable period, as it had been shown in animal studies that a better response was evoked by small doses spread over a period of days than by one large dose. The patients injected were cases of amenorrhœa in both married and unmarried women, patients from whom both ovaries had been removed, and attempts at the induction of labour. The following table summarises the results, cases which could not take the full two months' course having not been further analysed.

	Unmarried.		Married.
Cases treated	40	......	38
" having full 2 months course ..	32	......	30
" in whom menstruation started	10	......	18
" feeling better	30	......	29

In the successful cases slight bleeding usually occurred within a week or ten days of the treatment, sometimes amounting to a full period, and this was followed in three or four weeks' time by a perfectly normal period. After two months' treatment the periods continued to appear regularly and the patients all felt much better. This improvement in health, however, as also in the cases when menstruation did not occur, was partly due to psychological causes as excellent tonic effects were observed in many cases receiving normal saline injections who thought they were getting the active preparation. In three attempts at producing premature labour only one was definitely effected and the experiments were abandoned. Five cases of menopause were treated with definite improvement in all.

---

[1] Quart. Jour. Med., January, 1930, p. 213.

It will be seen from the summary that only 30 out of nearly 80 cases treated showed objective improvement, and the investigators expressly stated their feeling that the series was too small to form the basis of a valid opinion, and that at least 1000 cases of amenorrhœa should be treated before the material could fairly be assessed. Much larger doses must be given, they thought, particularly in the attempts at producing premature labour, before discarding the substance as useless, but this was impossible at present owing to the expense and labour involved in producing the material. They concluded by pleading for a thorough trial with objective results.

NEW METHODS IN SPINAL ANALGESIA.

Two papers at the Section of Anæsthetics of the Royal Society of Medicine last Friday produced some sound evidence of the value of spinal injections in the present state of knowledge. The first by Mr. Charles Donald gave a judicious and well-balanced account of the value of spinocain, the merits of which have been, as is so often the case with a new method, suffering from over-statement. Mr. Donald showed that in most respects spinocain is neither better nor worse than novocain. It has the advantage of being more slowly absorbed and therefore less toxic, but the extravagant claims made for it as regards exact localisation of analgesic effect and as regards absence of fall of blood pressure, or of subsequent ileus, were shown to be unfounded. In the other paper Dr. Howard Jones trod new ground with the use of large quantities of percain in dilute solution as an intrathecal injection. He stated that his account must only be regarded as a preliminary, but the results he detailed were excellent, and were borne out by the testimony of other speakers. Dr. Howard Jones's method is based on principles determined by the specific gravities of the cerebro-spinal fluid and of the injected liquid, and provide a logical means of affecting the anterior and posterior roots in accordance with the decubitus of the patient, and of localising the upward extension of the analgesia with sufficient accuracy for practical purposes. In upper abdominal work he cannot eliminate vagal effects when the stomach is handled (e.g., retching), but he can produce at will a perfect block of spinal nerve roots up to the second dorsal vertebra. The value of percain lies largely in the extreme dilution in which it is effective and the consequent absence of toxic effects from absorption into the general circulation. The condition of patients with percain is superior to that usual with novocain or stovaine. The after-headache does occur, but this and after-vomiting are certainly not more severe than those not uncommonly met with after the use of the former drugs and may be even less severe.

CONGRESS OF DERMATOLOGY AT COPENHAGEN.

The eighth International Congress of Dermatology and Syphilology is to be held in the Christiansborg Palace at Copenhagen from Monday, August 4th, to Saturday, August 9th, under the patronage of the King of Denmark and the presidency of Prof. C. Rasch. After a meeting of delegates on Monday afternoon and a reception in the evening, the Congress will be opened by the King at 9 A.M. on Tuesday, to be followed by a discussion on the Ætiology and Pathogenesis of Eczema, introduced by Darier (Paris) and Jadassohn (Breslau). On Wednesday morning the subject of Syphilis: Immunity, Reinfection, Superinfection, will be introduced by Truffi (Padua) and Wade Brown (New York). On Thursday morning dermatological cases will be demonstrated at the Rigshospitalet, and on Friday morning a discussion on Tuberculosis of the Skin and its Treatment will be introduced by Adamson (London) and Reyn (Copenhagen). Every afternoon except Thursday individual papers will be read and discussed; intending readers are asked to communicate before April 1st with the Secretary-General of the Congress, Dr. Svend Lomholt, Raadhuspladsen 45, Copenhagen, and to state if any projection apparatus is desired. A maximum of 15 minutes will be allowed for the reading of these papers, of which a short summary in English, French, German or Italian should be sent to the Secretary before June 15th. Foreign members wishing to take part in the Thursday demonstration of cases should apply to Dr. H. Haxthausen, Finsens med. Lysinstitut, before June 30th; accommodation for such patients will be provided gratis for two days in the skin department of the Rigshospitalet. A scientific exhibition will be held during the whole period of the Congress from 9 A.M. to 6 P.M. in the Kongens Ridehus at the Palace, the manager being Mr. C. B. Ingwersen, Danasvej 30, Copenhagen V., to whom applications for participation should be addressed. The Dansk Rejsebureau has undertaken to make arrangements for the accommodation of members of the Congress at very moderate figures and there will be a travel bureau enabling visitors to make tours in Copenhagen and excursions to Bornholm, Jutland, and Odense. The Danish State Railway is offering members of the Congress a reduction of 50 per cent. on their return tickets. The British delegates to the Congress are Dr. H. G. Adamson and Dr. Arthur Whitfield, Dr. A. M. H. Gray being local secretary.

THE ACTS OF RAHERE.

On March 11th a cast of actors, whose names are not announced, gave the first performance of the "Acts of Rahere," a play depicting the foundation of St. Bartholomew's Church and Hospital 800 years ago. Rahere was one of those "fiery particles" which have a lasting hold on the imagination. He was officially the Court jester of Henry I., and attained much influence while still a young man. After religious conversion he went on pilgrimage to Rome, and there during illness had a vision of St. Bartholomew, who told him to build a church and hospital in the Smooth Field, one of the most depressing and useless spots in the neighbourhood of London, a deserted swamp near the public execution ground. He promptly returned to England, discovered that the site he wanted was the King's and boldly asked for it, in spite of Henry's anger at his desertion. He not only gained his point but his Sovereign's interest and practical help, and he soon drew support in money and personal service from a large section of the population of London. This is the drama that the actors of St. Bartholomew's reconstruct every evening at 6 o'clock in aid of the project to build a new surgical wing holding 250 beds and an operation block with six theatres. The stage is the sanctuary of the old church itself beside Rahere's own tomb; the performance, in the candle-lit setting of this perfect Norman fabric, is extremely impressive.

Dr. Norman Scott Carmichael, Physician to the Royal Hospital for Sick Children, Edinburgh, has been appointed Surgeon Apothecary to the King's household at the Palace of Holyroodhouse.

The William Mackenzie Medal for 1929 for original contributions to ophthalmology of outstanding merit has been awarded by the custodians, The Glasgow Eye Infirmary, to Prof. J. van der Hoeve, of Leiden, Holland.

Dr. Carey F. Coombs will deliver the Lumleian Lectures at the Royal College of Physicians of London at 5 P.M. on March 20th, 25th, and 27th. His subject will be Syphilis of the Heart and Great Vessels, and members of the medical profession will be admitted on presentation of their cards.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCC.—THE TREATMENT OF HÆMOPTYSIS.

The Causes of Hæmoptysis.

NEARLY every student when asked the causes of hæmoptysis begins by describing "false hæmoptysis," coming from the teeth, the throat, and the larynx. A modicum of intelligence on the part of the patient and the doctor is sufficient as a rule to determine whether the blood is coughed up or not. If it is in streaks mixed with phlegm it must almost certainly have come from the lung; if it is in larger amounts it must come from the lung. The differential diagnosis between hæmatemesis and hæmoptysis is, of course, important, but not usually difficult, and for reasons of space will not here be discussed. Disastrous errors occur because hæmoptysis is ignored or its cause belittled. Hæmoptysis implies some pathological condition needing investigation. The commonest cause, apart from acute infections such as the pneumonias, is pulmonary tuberculosis. The diagnosis of this depends on symptoms, on bacteriological examination of the sputum and fæces, the temperature record, weight record, physical and X ray examinations. Frequently after a hæmoptysis the doctor, finding no abnormal physical signs in the chest, sends the patient to a laryngologist instead of making further investigations into the state of the lungs. There is practically no condition in the larynx which will produce a hæmoptysis of any appreciable amount. The following example is a not uncommon type of tuberculous hæmoptysis. Yet, in my experience, incredible as it may seem, the hæmorrhage would have been explained by many medical men in some other way; a true diagnosis might never have been made, and the subsequent course would have lent support to whatever false hypothesis had been formulated.

One evening a medical student coughed up over half a pint of blood. He was taking his finals and had appeared to be in normal health. His temperature after the hæmorrhage was slightly raised. His appearance was anxious. There were abnormal signs in the left upper lobe. Some of the clotted blood was taken for examination. Tubercle bacilli were found. In three weeks his temperature was normal, he was putting on weight, the abnormal physical signs had entirely disappeared. The X ray picture, taken within six weeks of the hæmoptysis, was absolutely normal, and repeated examinations of the sputum did not reveal tubercle bacilli again. He went to a sanatorium for a time, returned, became qualified, and has for some years now remained in robust health.

If it were not for the first bacteriological examination in this case the proof positive would have been lacking. Nevertheless, whether tubercle bacilli are found or not these hæmorrhages are almost always of tuberculous origin, except when they are due to something much worse and much rarer—namely, bronchiectasis or malignant growth.

After tuberculosis we come to rarer causes. Other chronic infections must be considered — non-tuberculous fibrosis, bronchiectasis, and such rare conditions as actinomycosis and broncho-pulmonary spirochætosis or spirillosis. There is a type of bronchiectasis, the chief symptom of which is not expectoration but recurrent hæmoptysis, sometimes profuse. Without a lipiodol injection exact and positive diagnosis is impossible. After bronchiectasis come neoplasm, infarct of the lung, and abscess of the lung. Infarction is especially common with mitral stenosis, but may occur with phlebitis of any systemic vein, particularly of the femoral vein. Infarction of the lung may occur before any pain or œdema is obvious in the leg. Hæmoptysis is also possible in intense congestion from back pressure, and possibly from local thrombosis in the lung itself. Other causes are aneurysm, foreign body, certain parasites, such as distoma, &c. Injury, of course, may cause hæmoptysis; not only the obvious bullet wounds, sword thrusts, and bayonet stabs of the text-books, but severe blows and an unrecognised fracture of the ribs and clavicle. High blood pressure may be the cause of hæmoptysis. It may occur in certain blood disorders—purpura, hæmophilia, scurvy, leukæmia. Occasionally one meets with a brisk hæmoptysis in elderly people; after full investigation, and having excluded tuberculosis, new growth, and high blood pressure, all that one can say is that there appears to be an old scarred area. The origin of this may have been an antecedent tuberculous or non-tuberculous infection at some time.

Measures for Relief.

In some cases treatment of the cause may stop the hæmorrhage. For example, the relief of congestive heart failure by venesection, cupping, heart "tonics," and so on, or the proper treatment of scurvy. But these are infrequent causes of hæmoptysis. Unfortunately, we do not know how to prevent infarction, but fruit juice and citrates are worth trying. Hæmoptysis in high blood pressure cases may be severe and cause much distress and anxiety, and be very difficult to control. Venesection may be called for, and here, if anywhere, the vasodilators would seem theoretically to be indicated; the nitrites, trinitrin, erythrol tetranitrate, amyl nitrite, &c., hot mustard foot baths, and such remedies as ipecacuanha and emetine are worth trying. The coagulants to be mentioned later are, of course, theoretically contra-indicated, for fear of producing thrombosis in other parts to which the patient is already predisposed. The largest hæmorrhages come from tuberculous and bronchiectatic cavities, occasionally from growths and from rupture of an aortic aneurysm. For the last mentioned very little can be done beyond rest and the giving of some form of opium to allay restlessness. It is chiefly the hæmorrhages from tuberculosis or bronchiectasis that we shall be called upon to treat. The number of remedies is legion. Bleeding tends to cease spontaneously. For this reason many remedies have gained an undeserved reputation.

A sudden hæmorrhage may occur without any warning. The patient is terrified. The first thing, therefore, is to try to allay anxiety by giving a small injection of morphia, just enough to calm the patient but not sufficient to suppress in the least the cough reflex. If care be not taken in this respect there is a great danger of blood being aspirated into other bronchi and flooding the whole lung with blood, thus setting up a pneumonic condition. Some give codeine, gr. 1/7th (though why 1/7th, except to confuse the student, I do not know), two or three times in the day, instead of morphine. The patient must be so arranged that he can get rid of the blood from his mouth with the least possible exertion. An ice pack on the chest is comforting for the patient, and the relations, and if it does no good it does no harm. The position should be a comfortable one. Let there be no hard-and-fast rule. A semi-sitting posture may be the best. Rigid insistence on absolute rest in the flat position is absurd.

If the bleeding continues one or more of the following remedies may be employed. The action of none of them can be guaranteed, but no apology is made for the length of the list because we must do something, and from the urge within us to do this something, and for the sake of the patient, and the relatives, it is of great help to have several remedies at our disposal. An old simple device and one that may be effective is half a teaspoonful of common *salt* in water, given by mouth. Salt may also be given intravenously, 5 c.cm. of a 10 per cent. solution. Gravesen recommends *calcium chloride* 20 c.cm. of a 15 per cent. solution, given intravenously slowly and with great care not to get it into the tissues as it is corrosive. An injection of *hæmoplastin* may be given. The objection to this, however, is the possibility of an irritating rash or serum sickness. This, when it occurs, may be controlled by adrenalin, but adrenalin given hypodermically has been condemned in hæmoptysis. *Coagulen-ciba*, 5 c.cm. may be given hypodermically. This is said to contain bovine blood-platelets and not to cause serum reactions. A. J. Morland, however, reports a case where the patient, after an injection, experienced a sensation of lumps all over his body and these would appear to have been of an urticarial nature. This same author has injected coagulen-ciba 5 c.cm. and 10 c.cm. directly into a cavity in a case of severe, recurrent, and dangerous hæmorrhage, apparently with dramatic effect, and this is well worth trying in serious cases where there is a large cavity in a known position, or even as a hazard, if things are desperate. Two other substances which claim to increase the coagulability of the blood may be mentioned: *thromboplastin* and *fibrogen*. They must be used subcutaneously or by mouth, or both, but not intravenously. *Ergot* has been extolled by certain optimistic clinicians, but on pharmacological grounds should do more harm than good. *Emetine* in gr. ¼ doses, given hypodermically three or four times in a day, is worth trying. *Amyl-nitrite* inhaled is both extolled and condemned. It has the support of many clinicians. The same applies to *nitroglycerin* in 2 to 4 minim doses. *Oil of turpentine*, minims 20, in an emulsion every four hours, is a time-honoured remedy which does no harm. *Adrenalin* cannot be justified on experimental grounds. Given intratracheally, however, by the oral route, over the back of the tongue, as one gives an oral lipiodol injection, it is said to be most effective. This is perhaps true, but the obvious objection is the impossibility of doing it in an emergency when blood is welling up into the mouth. In a calm interval, however, it might be worth trying. *Binding the limbs*, but not for too long a period, may tide the patient over a critical period. Even *blood transfusion* may have to be considered.

Artificial Pneumothorax.

If none of these things acts, and matters are becoming urgent, there is only one method that is likely to be effective and that is the production of an artificial pneumothorax. In hospital where the apparatus is available it should not be used only as a desperate resort. If it were known from which side the blood was coming it would be used early, but it is not always possible to determine this. Even so, it would be better to induce a partial bilateral pneumothorax than to do nothing. The time is long overdue when every practitioner of medicine should know the inestimable value of such induction. If the affected lung can be compressed by this procedure, all bleeding is stopped and its recurrence absolutely prevented.

For recurrent small hæmorrhages, whether from tuberculosis or bronchiectasis, if the disease is unilateral, some form of collapse therapy is the best. First and foremost comes artificial pneumothorax. This is simple, painless, and safe. If not hindered by adhesions, it will stop hæmorrhage and it will promote healing. There is no point in delaying this treatment, for everything is to be gained by it. If, because of adhesions, an artificial pneumothorax cannot be obtained, phrenic evulsion and thoracoplasty may have to be considered. Apart from these measures the patient must avoid strains, excitement, and alcohol. Yet, not infrequently, hæmorrhage will occur when the patient is at complete rest. Calcium may be given, for example, calcium chloride grs. x., calcium lactate grs. x., three times a day, and this, I believe, to be of great help. In conclusion, the fear inspired by a big hæmoptysis must not be forgotten. Our efforts to control a hæmorrhage must never subject the patient to further risk; insistence on the prone position, for example, may cause great suffering and almost choke the patient, and, moreover, make it difficult for him to eject the blood. An overdose of morphia may be disastrous by promoting aspiration, while injections of serum may produce intolerable urticaria. While one should never remain passive and inactive in these cases, a fussy interference may do more harm than good. The injection or application of one of the above-mentioned remedies at regular intervals undoubtedly gratifies both the patient and the relations. The best way to treat a hæmoptysis is to prevent it. This may be impossible, as hæmoptysis is sometimes the first symptom. When there is a known focus from which a recurrent hæmorrhage is arising, artificial pneumothorax treatment should be attempted without delay in some cases, even if the disease is bilateral.

STUDIES OF VIRUS DISEASES.

THE MEDICAL RESEARCH COUNCIL'S SURVEY OF THE POSITION.

No part of the work directly promoted by the Medical Research Council has greater biological interest at the present time, or more vital practical importance for the cure and prevention of disease, than the inquiries now being made into various diseases in animals and man caused by the so-called "viruses." These inquiries are concerned with an invisible underworld of bodies that in size stand somewhere between the largest known molecules of dead organic matter and the smallest microscopic bacteria. These cannot be seen as definite structures by ordinary microscopic means, and the relation to them of certain objects made visible by special optical methods is still a matter of discussion. They are called "filter-passing" because many of them will traverse a filter fine enough to hold back and strain off ordinary bacteria from a fluid containing them.

Whether these "viruses" are organised as minute, ultra-microscopic bodies is still an open question; in any case, they are presumably too small to have an organisation similar to that of such cells as have hitherto been regarded as primary units of living matter. Nobody has yet succeeded in preparing an artificial fluid which will, by itself, provide conditions in which these viruses will reproduce themselves and multiply; some of them, however, will grow in artificial conditions if a piece of surviving tissue, taken from a freshly killed animal, is added to a suitable medium. It seems to be characteristic of a virus that it can multiply only in the presence of living cells which it can infect.

When the virus causing any disease is introduced into the animal, or the plant, in minute quantity, there may occur a rapid, unseen, and unexplained multiplication of it throughout all the parts of the organism attacked, since a minute portion of any of those parts will be found able to infect another similar organism.

TWO CONVERGING LINES OF EFFORT.

Those now working with viruses are under difficulties very like those that confronted bacteriologists two generations ago, before they had found adequate methods of microscopic study and of artificial cultivation. At present their endeavours may be thought of as following two converging lines of effort: (1) practical devices are sought by which empirical imitations may be made of the immunity to a second attack of a virus disease that most commonly follows recovery from the first attack under natural conditions; (2) investigation is made by every known method into the physical properties and natural history of the virus itself.

Attempts to Produce Immunity.

The particular historical method of using cow-pox as Jenner did to immunise against small-pox in man has not so far been found applicable to other virus diseases. Small-pox adapted to living in the tissues

MEDICAL SOCIETY OF LONDON.

ANNIVERSARY DINNER.

THE 157th anniversary dinner of the Medical Society was held on March 6th at the Hotel Cecil, the President, Mr. Donald Armour, presiding. The guests included the President of the Royal College of Physicians of London, the Master of the Society of Apothecaries, the Regius Professors of Medicine at Oxford and Cambridge, the Directors-General of the Navy, Army, and Air Force, the President of the British Medical Association, Mr. Lucian Pacaud (High Commissioner for Canada), Colonel J. L. Ralston (Minister of National Defence for the Dominion), Mr. W. C. Noxon (Agent-General for Ontario), Mr. Wilson Cross (President of the American Society in London), the Presidents of the Royal Society of Tropical Medicine and Hygiene, Harveian Society, Medico-Legal Society, Hunterian Society, West London Medico-Chirurgical Society, and Chelsea Clinical Society, the chairmen of the National Hospital, Queen-square, and the West London Hospital, Sir Lindsey Smith, and the Editors of *Canada*, the *British Medical Journal*, and *The Lancet*.

Sir Humphry Rolleston proposed the toast of the Medical Society of London. A good wine, he said, needs no advertisement, and the Medical Society admirably illustrates the law of the survival of the fittest, for, when founded in 1773 for 30 physicians, 30 surgeons, and 30 apothecaries or general practitioners, there were quite a number of other medical (or *physical*) societies, while it is now the only one left. It is the oldest medical society in London with the solitary exception of the Guy's Physical Society, and it is interesting to note, as showing that Guy's men are very clubbable men, that in Medley's picture of the 22 Founders of the Medical Society a quarter are Guy's men. Among the virtues of the Society is celibacy—though not for want of offers to join up nearly a quarter of a century ago with the Royal Society of Medicine—and its stern virtue no doubt played part in its contrary decision. Medley's portrait also shows another tradition of the Society now fallen into desuetude, and the President will perhaps explain why that high officer no longer wears his hat at all meetings. The Society is now in its 157th year, and has recently flourished in a remarkable degree, increased mightily in its members, and more than lives up to its high traditions, results due to the devotion of its officers. With its chief officer, Mr. Donald Armour, this toast is coupled. He is a great surgeon, exploring the brain with high intent or laying bare the misdeeds of the spinal cord—he was indeed the first Lettsomian lecturer to take that region of surgery as his subject.

Mr. Donald Armour, in reply, said that in thanking the proposer of the toast, who, himself, had once occupied the Presidential chair of the Society, for his flattering references, he would be brief in deference to the Society's rules. When that altruistic Quaker, he continued, John Coakley Lettsom, founded the Society, he said of its utilitarian objects: "Nothing has contributed more to the advancement of science than the establishment of literary societies; these excite a generous ardour in liberal minds, and raise even envy itself into useful emulation." Having launched the Society, it was necessary to provide it with rules and regulations. Judging from the numerous and protracted meetings held for this purpose, it was obvious that there were differences of view, but Lettsom, whom his biographer, Pettigrew, has described as "the uniform pacificator of all differences . . . rarely failing in effecting an adjustment of them," lived up to his reputation, and order finally came out of confusion; but it is significant, as proving the length and warmth of these discussions, that the first scientific paper read before the Society by its first President, Dr. John Millar, was entitled, "Observations on the Loss of the Voice." Having settled their differences and recovered their voices, the Society settled down to pursue its vocation in peace until, in 1786, an Irishman, one Dr. James Sims, was elected President. He is described as "a good-humoured, pleasant man, full of anecdote, an ample reservoir of good things, and for facts and figures a perfect chronicle of other times." In transatlantic parlance this Irishman must have been a "good mixer." At any rate, he mixed the ballot box so successfully that he occupied the Presidential chair for 22 consecutive years. Being an Irishman, his was at first probably a beneficent despotism. But later, when it became an autocracy, the inevitable happened—revolution, fortunately, a bloodless one. Some of the younger Fellows, despairing of the retirement or demise of this Irish dictator, broke away, and in 1805 founded the Royal Medical and Chirurgical Society, the nucleus of the Royal Society of Medicine. Having purged itself of malcontents, the Medical Society of London has continued ever since along peaceful lines, growing yearly in strength and stature, and always adhering to the purposes of its foundation, as laid down by Lettsom himself—namely, "to give the practitioners in the healing art frequent opportunities of meeting together, and conferring with each other concerning any difficult or uncommon cases which may have occurred; or communicating any new discovery in medicine, which has been made, either at home or abroad." And we still pride ourselves upon what I may call, professionally speaking, the cosmopolitan character of our meetings. Unlike our rebel offspring, now grown to Gargantuan proportions, we are not "sectionists," we do not work in water-tight compartments, we do not encourage specialism as such, our discussions are not limited to any part of the human body, to any age, nor to either sex. In this Society we have a small and jealously guarded list of Honorary Fellows, and we have made a single addition to it this year, the first in three years. I refer to Sir Arthur Keith, just now absent in Egypt; we are anticipating with the greatest pleasure his oration before the Society in May on "Modern Medicine and Evolution." I conclude my remarks with a confession, which is in no sense an appeal; but I hope that it will be an appealing confession. In our home we have a Cinderella, waiting these many years for the clothing that her beauty and her rarity deserve. In hopeful expectancy we anticipate the coming of some fairy godfather, or godmother, or both, who will provide her with proper coverings to preserve her for all time. I refer to some of the priceless contents of our library. They comprise thirteenth century manuscripts and printed books dating from 1471. I should like to start a "free-trade" crusade—free trade between the lovers of books, who have money to spare, and our library that needs it for the care of our valuable books and manuscripts. Thus our Cinderella might have her fairy slippers, and the Fellows of the Medical Society live happily ever after.

The toast of the Guests was proposed by Dr. Eustace M. Callender, also a past-president of the Society, who referred to the high position occupied by many of their guests, and who coupled the toast with the name of Colonel Ralston, whose great abilities as legislator and lawyer, he said, were now recognised as his qualities as soldier had been recognised throughout the recent war. Colonel Ralston, in his reply, referred to the presence of Canadian guests as due to the long and high association of the President's family with the Dominion, and showed that a sound legislator and a brave soldier could be also a witty man.

CITY OF LONDON MATERNITY HOSPITAL.—A series of post-graduate lectures will be given at this hospital at 5 P.M. on Tuesdays from March 25th to June 10th. The lecturers will be Dr. Abernethy Willett, Mr. R. Christie-Brown, Mr. McKim McCullagh, Mr. Arnold Walker, Mr. Harold Burt-White, Dr. Sydney Owen, and Dr. H. C. Lucey.

Correspondence.

"Audi alteram partem."

VARIOLA MAJOR AND MINOR.

To the Editor of THE LANCET.

SIR,—I have read with much appreciation the paper by Dr. R. W. Jameson, appearing in your issue for March 8th. I wish strongly to support his contention that the time has come when the distinction between the two forms of small-pox, major and minor, should be officially recognised. As he points out, whilst it may not be easy to decide the nature of the first case in an outbreak it should always be possible to decide after a series of cases have occurred. I believe that no real doubt exists about the nature of any outbreak which has occurred in this country since the war, and it is only in the post-war period that the existence of variola minor as a distinct form of small-pox has been suspected. Dr. Jameson draws attention to the confusion and other disadvantages resulting from the present plan of calling both forms "small-pox," without distinction. We may well ask what value our present case-mortality statistics will have in years to come when it will be impossible to know what proportion of the cases lumped together as "small-pox" were of the major or minor variety respectively. The terms "variola major" and "variola minor" have, as Dr. Jameson states, been accepted in the last Decennial International Conference on the Nomenclature of Causes of Death, and I venture to suggest that the Ministry of Health would be moving in the right direction if they invited medical officers of health in reporting small-pox cases to specify whether the cases were major or minor.

I am, Sir, yours faithfully,

C. KILLICK MILLARD,
Medical Officer of Health.

Health Offices, Leicester, March 11th, 1930.

PROTECTION AGAINST MEASLES.

To the Editor of THE LANCET.

SIR,—Your interesting leading article last week is a valuable contribution in the study of immunity, but raises one or two practical considerations in relation to private practice. "The importance of this work," you say, "lies in the fact that it brings the sero-prophylaxis of measles within the range of measures practicable to the family doctor, for one or other of the parents is almost certain to have had measles, and thus the donor is immediately available." That is to say, we are now considering the individual child or family.

That a parent's serum may still carry the immunising properties is so convenient that the procedure should be quite simple. But it is an important consideration how long any such passive immunity may last; because measles is a very harmless disease in small children, when efficiently treated—that is to say, in bed, in a room that is really warm, with a minimum of washing—whereas in young adults it tends to be much more serious, and most of us know of fatal cases. I believe that the most experienced medical officers of public schools are afraid of the boys who have not already had measles. I believe the evidence that measles should be treated at home during childhood, rather than at school or in lodgings or hospital later on, is so convincing that prophylactic inoculation against measles, producing a short-lived passive immunity, is a doubtful advantage for young children, who might otherwise have developed an active immunity by having measles at home with no disadvantage other than the loss of a few Christmas parties or some day-school lessons.

A short-lived passive immunity might be of the utmost importance in exceptional circumstances—for example, shortly before a scholarship examination or a family holiday—but for the latter the possibility of only obtaining an "attenuated measles after a long incubation period" might make the dates more inconvenient. A fellow student of mine, some 30 years ago, developed measles at an awkward time in his medical curriculum, and his father, who was a doctor, told me he would deliberately expose his children to the infection of such illnesses, if he could have his time over again. Without going as far as this, if I were advising the medical profession with regard to their own children, I should say that the first time a child is exposed to the infection of measles is probably the most convenient and the safest time to have the disease. To prevent that attack, with a short-lived immunity, leaves an added responsibility for the future, and should only be attempted when some exceptional circumstances make measles particularly unfortunate at that season.

When a child develops measles in a hospital ward sero-prophylaxis would be invaluable for the other children, because the administrative responsibilities of measles in a children's ward are very serious.

I am, Sir, yours faithfully,

Derby, March 10th, 1930. HUGH BARBER.

SOCIAL CUSTOMS AND INFANT MORTALITY.

To the Editor of THE LANCET.

SIR,—Indian obstetrical methods and social usages have come in for severe and entirely unmerited criticisms in THE LANCET in a note on a contribution to the *Hibbert Journal* by Miss Eleanor Rathbone entitled "Has Katherine Mayo Slandered Mother India?" Miss Mayo's book having received previously a favourable notice in the same paper. We did not take these uninformed and biased criticisms seriously, but now they have begun to colour all official and unofficial health reports.

The constructive suggestions made in THE LANCET about the education of women and the training of the indigenous *dai* are valuable, if by education is meant real education; but it seems almost incredible that THE LANCET, while discussing the death-rate of Indian infants, should have sedulously omitted all reference to the appalling economic conditions, and trotted out Indian social customs as the sole cause of the high Indian death-rate. That social customs, good, bad, or indifferent, have comparatively little effect on the health of the people and that proper nourishment is the all-engrossing factor, form an obvious proposition. In 1925 the Mississipi inundated a large tract of country and the Government of America pressed into service a flotilla of aeroplanes and dropped tinned provisions to the sufferers. A serious development of pellagra occurred, not as a result of starvation but due to lack of vitamin B in the diet during the short period of relief. Who argues that this absence of stamina on the part of the American people was to be ascribed to their social customs? Also who has ever heard in India of the occurrence of a single flood leaving the people in the grip of pellagra? Judged by this incident Indians have the greater stamina, so that, if social customs are the dominant factor, American social customs make a poor show by comparison. Again, during the great European war the central States of Europe were compelled to go without some only of the essential foodstuffs for not even four years. This short course of restricted diet broke down the constitution of the populations so completely that for years afterwards Vienna, for example, showed an immense rise in the occurrence of rickets and tuberculosis. If this is to be laid at the door of social customs the sooner European social customs are improved the better. The people of India have, with their social customs, been inured to hardships and privations of every sort, and from their cradle been faced with famine and flood.

I undertook last year a private census of 800 births amongst persons with an average income of L.200 a year, all of whom adhered to traditional obstetric methods and the infamous *dai*. The deaths numbered 28·75 per 1000, whereas the general death-rate in England among infants is 70 per 1000. My private figures are corroborated by an official investigation undertaken at the instance of the Director of Public Health, Madras (*Indian Medical Gazette*, October, 1929). In four cities of the Madras Presidency (Madras, Madura, Coimbatore, and Trichinopoly), taking an unselected population of 183,000 (predominantly Hindu), there were over 7300 births in all. It was found that the death-rate of infants varied inversely with the income. Thus in families with incomes of Rs.25 or less, the death-rate was 120 per 1000. In those with incomes between Rs.25 and Rs.50 it lessened to 105 per 1000, while in families with incomes above Rs.50 per month (corresponding to the magnificent sum of £3 17*s.* per month) the death-rate dwindled down to 84 per 1000—i.e., only two-thirds of the normal death-rate in the case of the poverty-stricken and half-fed masses.

The results of the Madras investigation are entirely in keeping with those of the private inquiry held by me, and, if figures can prove anything, they establish beyond the possibility of a doubt that the stomach alone controls the mortality of infants, and that all the other factors combined count but as a feather in the balance. It passes all sober comprehension how anyone, least of all a medical man, professing to talk about the causes of a high death-rate of suckling infants and their mothers, can talk only of deficient medical aid and unhygienic social customs, oblivious of the abject and crushing poverty, of the meagre and poor dietary, leading to chronic malnutrition, verging on to starvation, and of the recurrent horrors of widespread famines and ravaging floods, accentuated by the no less fell ravages of that scourge, malaria.

Perhaps it is not too much to hope that, in a scientific paper of the standing of THE LANCET, the issue here raised will be met squarely.

I am, Sir, yours faithfully,

NALINI RANJAN SEN GUPTA, M.D.

Feb. 15th, 1930.

*** From Dr. Sen Gupta's communication we have only been able to find space for the relevant paragraphs, which correct, as he believes, the faulty impression given by the editorial article in THE LANCET.—ED. L.

SPINAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I have followed the recent correspondence with interest and with such understanding as the very involved communications allowed. The recent paper on high spinal anæsthesia by Koster and Kasman is startling in its simplicity, and if their results are confirmed, the position should be freed from much of its present obscurity. In the meantime, whatever may be the effect of anæsthetic solutions on the respiratory centre, it is no longer possible to regard paralysis of the diaphragm as a cause of death. I have under my care a patient whose diaphragm is completely paralysed as a result of bilateral phrenic evulsion and whose respiration is in no way embarrassed. Similar results have been recorded by continental surgeons, and the case is recorded merely because it seems to call for some measure of revision of the current theories of respiration.

I am, Sir, yours faithfully,

Omdurman, Feb. 22nd, 1930. L. O'SHAUGHNESSY.

FOOD OR DRUG?

To the Editor of THE LANCET.

SIR,—It is indeed disappointing to find THE LANCET ranged on the side of a bureaucracy which is interfering, I submit unwarrantably, with the professional freedom of practising doctors. The narrative of "one of the four offenders," as set out in your last issue surely reveals a very disquieting state of affairs. I think the inference is inevitable, that these prosecutions for excessive prescribing are largely the result of the arrangement made in 1927 by the then Minister of Health with the dispensing pharmacists. Prior to that date the Drug Fund had always been overdrawn, the natural consequence of its essential inadequacy, but the overdraft had been to some measure met by discounting the bills for dispensing presented by pharmacists on the panel. This very unfair treatment of the pharmacists was remedied by the agreement of 1927, and the pharmacists' fees for dispensing are now a first cost upon the Fund. But there is now actually less money to be spent upon drugs than before and it has become increasingly impossible any longer to camouflage the inherent bankruptcy of the National Health Insurance Fund.

There is a very pertinent observation upon this kind of treatment of panel doctors under the National Health Insurance Acts in Lord Hewart's recent book "The New Despotism" (p. 50). He writes, "'Excessive prescribing,' an offence wholly unknown to the law, which consists in prescribing for the patient medicines that are either too expensive in quality or too liberal in quantity, is one of the things for which a doctor may be penalised. One might think that, for a person who is bound by law to insure and pay contributions under the Acts, the best medicine ought to be prescribed in illness. But apparently that is not always the view of the department. One might wonder whether, in this matter, the interests of the patients are adequately taken into consideration."

You write in your annotation of March 1st, "Those who administer the Acts are agreed that insured persons should get as good treatment as do private patients," but this statement seems to conflict with another sentence in the same leader: "The referees held that the wholesale administration of cod-liver oil *in insurance practice* (the italics are mine) was only legitimate as an experiment, conducted under experimental conditions." This dictum is rather cryptic, but it expressly makes a distinction between insurance and other practice.

I may say that I have asked a question in the House upon this case and have had a personal talk with the Minister of Health, who, while not committing himself in any way, has shown an attitude of sympathy contrasting favourably with the curious aloofness, not to say hostility, displayed by the official medical journals to the practitioner thus penalised.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

House of Commons, March 11th, 1930.

*** As a reference to our Parliamentary Intelligence will show, the power to withhold remuneration from insurance doctors on account of excessive prescribing has been exercised by the Ministry of Health since medical benefit first came into operation in 1913. This power in the Minister's view involves no limitation of the scope of medical benefit. Whether or no the practitioner accepts this dictum he must realise that he can only draw more than his share of a limited fund at the expense of the patients of neighbouring practitioners. A correspondent last week convicted us of a regrettable slip in our statement of the composition of the tribunal. Unlike the committee which inquires into complaints against a practitioner, there is no requirement that the referees in these prescribing inquiries should include a barrister or solicitor. The two requirements are that they shall not exceed three in number, and that they shall not include an officer or officers of the Ministry. The same correspondent last week made the point that the referees are appointed by the Minister and are therefore not independent. This has, of course, applied from the commencement of medical benefit to all bodies set up for quasi-judicial purposes under the N.H.I. Regulations, including the most serious case of all, that of removal from the medical list, and there has been no evidence hitherto that insurance practitioners generally regard it as unsound. While the regulation leaves the door open for the appointment as referees of laymen, it has been the practice so far to rely entirely on doctors, in view of the essentially medical nature of the question to be determined. The chairman of the committee of referees has always been a chairman of a panel committee who is known to have paid special attention to this subject; wherever possible the second referee has been a consulting physician with similar experience, and the third has always been a member of a panel committee.—ED. L.

REST IN THE TREATMENT OF GONORRHŒA.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Priest, the point I wished to make was this. No longer should a doctor, when undertaking to treat a case of acute gonorrhœa, acquiesce without strong protest in foregoing his demand of absolute rest on the patient's part. It should be emphatically pointed out to the victim that refusing this, a most essential factor for obtaining an early and successful result, he was laying himself open to, and must take the responsibility for, any serious complication which was more than likely to ensue as a result of that refusal. Too often in the past this all-important demand and explanation has not been stressed, the patient's natural objection to lying-up being taken for granted, with the ultimate result that the doctor receives no recognition of his well-meant leniency, but on the contrary a discontented patient retails and details a long and disparaging story of the treatment received to a "second opinion."

I am, Sir, yours faithfully,
JAMES B. BYLES.

St. James's-place, S.W., March 4th, 1930.

TECHNIQUE OF TRANSFUSION.

To the Editor of THE LANCET.

SIR,—As a therapeutic agent the practice of blood transfusions has very greatly increased of late years. There can be no question but that it is of immense value and in some cases a transfusion may be repeated several times, and by whatever method it is done the mere prick of the needle gives no discomfort to the patient. The practice of introducing the needle into any type of vein can be easily acquired with a little practice; yet it is an extraordinary fact that the old method of dissecting out the vein is still being used. It wastes time, causes some discomfort to the patient, leaves a scar, and the disadvantage increases when several transfusions must be given. I have never yet seen a vein, provided sufficient time and trouble are taken to work it up, when it was necessary to dissect it out. It is surely time that this old and obsolete method should be given up.

I am, Sir, yours faithfully,
H. M. M. WOODWARD.

Harley-street, W., March 1st, 1930.

TAMWORTH HOSPITAL CONTRIBUTORY SCHEME.—Tamworth Hospital, which has had its own contributory scheme, has been compelled by financial considerations to join the big Birmingham scheme. Last year Tamworth raised £3617 in weekly pence, but so many contributors were in hospital for operations or were in-patients of the Birmingham hospitals, whose treatment had to be paid for by the scheme, that there was a loss on the year's working of £374. Birmingham thus received £2284 which left an insufficient balance upon which to run the hospital. In future, Birmingham will pay £3 a week for any patient it sends to Tamworth Hospital, the latter defraying medical and surgical fees.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. H. McDowall is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lt.-Comdr. J. R. Brennan to be Surg. Comdr.

Surg. Lt. R. R. Baker to be Surg. Lt.-Comdr.

The following appointments are made: Surg. Lt.-Comdrs. R. W. Mussen to *Pembroke*, for R.N. Hospital, Chatham, and as bacteriological specialist, and H. Brown to *Pembroke*, for R.N. Barracks, Chatham; Surg. Lts. W. P. E. McIntyre to *Effingham* (on recommg.), L. P. Spero to *Vernon*, and D. C. Drake to *Godetia*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. S. B. Levy to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Lt. G. L. Grieve is placed on the half-pay list on account of ill-health.

Lts. J. F. Wilde and W. A. Kerr (temp. commns.) to be Capts.

J. C. Macfarlane to be Lt. (on prob.).

TERRITORIAL FORCE.

Lts. R. Pollok and W. R. Ward to be Capts.

To be Lts.: G. A. F. Holloway (late Offr. Cadet, Univ. of Lond. Contgt., Sen. Div., O.T.C.), D. N. Nicholson (late Cadet, Edinburgh Academy Contgt., Jun. Div., O.T.C.), and P. J. May.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. J. Kerr to be Capt.

ROYAL AIR FORCE.

The undermentioned Flight Lieutenants are granted permanent commissions in this rank: A. L. St. Aubyn McClosky, J. M. Ritchie, and B. B. Kennedy.

Air Vice-Marshal David Munro, Honorary Surgeon to the King, is placed on the retired list at his own request.

Flight Lt. J. R. Williams (Temp. Capt., General List, Army, Dental Surgeon), relinquishes his temporary commission in the R.A.F. on completion of service.

INDIAN MEDICAL SERVICE.

Capt. A. Ba Thaw to be Maj.

Lts. W. J. L. Neal (prov.) and B. Shanker to be Capts.

Lt. (on prob.) V. T. J. Lynch relinquishes his prob. appointment.

COLONIAL MEDICAL SERVICES.

Promotions and Transfers: Dr. P. S. Selwyn-Clarke, Chief Health Officer, Federated Malay States; Capt. A. V. Greaves, Bacteriologist, Hong-Kong; and Dr. B. M. Johns, Professor, Clinical Surgery in the College of Medicine, Singapore.

The following new appointments have been made: Dr. W. C. O. Hill, Professor of Anatomy, Medical College, Ceylon; Dr. F. W. Gilbert, M.O., Northern Rhodesia; Dr. E. N. O'Neill, M.O., West African Medical Staff, Sierra Leone; Dr. D. R. McPherson and Dr. H. B. C. Wallace, M.O.'s, Straits Settlements.

DEATHS IN THE SERVICES.

Lieut.-Colonel George Hart Desmond Gimlette, C.I.E., late I.M.S., died at Southsea on March 7th, aged 74. He was the son of the late Fleet-Surgeon Hart Gimlette, R.N., and qualified with the M.R.C.S. Eng. and L.S.A. in 1877. Two years later he graduated M.D., M.Ch. at the Royal University of Ireland and joined the Indian Medical Service. In 1882 he took part in the Egyptian campaign and was present at the engagements of Tel-el-Kebir and Zagazig (medal with clasp and the bronze star). Till the autumn of 1883 he was employed in Egypt on special cholera work and afterwards went to Khatmandu as Residency Surgeon and ex-officio Assistant Resident. In 1891 he became Agency Surgeon in Baghelkhand, and subsequently he went to Indore in the same capacity. From 1901, when he was made a C.I.E., to 1908 he was at the Hyderabad Residency. He retired in 1910, but during the late war he served as P.M.O. of H.M. hospital ship *Sicilia*, and in France, Egypt, and Gallipoli. In 1917 he was re-employed in the I.M.S. as Residency Surgeon, Mysore, but afterwards returned to military duty in Mesopotamia.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE MENTAL TREATMENT BILL.

ON Thursday March 6th, the Mental Treatment Bill was further considered by Standing Committee A of the House of Commons. Mr. CECIL WILSON was in the chair.

Boarders "Incapable of Volition."

On Clause 2 (notice of reception, death, and departure of voluntary boarders, and provisions as to boarders who become incapable of volition).

The debate was resumed on the amendment moved at the previous sitting of the Committee by Sir Boyd Merriman to leave out the word "volition" in Subsection (3) and to insert instead thereof the words "voluntarily submitting himself to treatment."

Sir BOYD MERRIMAN said that the Minister of Health had now put down on the Paper a series of amendments which really met the point which he (Sir Boyd Merriman) was trying to raise, but in a slightly different way. The Minister was suggesting the words "expressing himself *as willing or unwilling to continue to receive treatment.*" The doctor would have to express himself in terms that he found the patient incapable of expressing his willingness and that would be the test. He (Sir Boyd Merriman) saw no objection to the form of words, but he would like to make this qualification, which applied to either form of words, that it might be necessary to make it quite clear that this incapacity was due to mental disorder. That point might, however, be left over for further consideration on the Report stage.

Mr. GREENWOOD (Minister of Health) said that he gathered that the Committee would be willing to accept his alternative form of words which were almost precisely those which would have been used in the definition had they defined the term "incapable of volition" later in the Bill. The words had been carefully considered in the light both of the medical and the legal issues involved. He would certainly look into the qualification mentioned by Sir B. Merriman.

Sir BOYD MERRIMAN withdrew his amendment.

Mr. GREENWOOD moved his alternative form of words, which were agreed to.

The "Ins" and "Outs."

Lieut.-Col. FREMANTLE moved in Subsection (3) to leave out the words "one month" and to insert the words "six months." He said that this was to meet the case of the patient, who, coming in as a voluntary patient, lost volition. As the Bill stood it recognised that there might be a chance of matters changing within a month, and consequently that period was given for the patient to change his condition without having to be certified or discharged. Medical experience showed that one month was not long enough for this purpose. That was the deliberate view of the medical superintendents and was also the experience of the London County Council. He would, therefore, ask the Minister if it would not be possible to enlarge the period to six months so as to give the cases which were medically described as the "ins and outs" a chance.

Mr. GREENWOOD said that it was a very serious thing where a person had gone voluntarily into an institution, and then later if he became incapable of expressing himself as to whether he wanted to go on being treated there or not, to detain him for a long period. He thought in view of Clause 5, where treatment would be available without certification, the Committee would be well-advised to let the period of one month stand, because he would be sorry if the question of the liberty of the subject were to be raised again.

Dr. HASTINGS said that the matter did not seem quite clear as the Minister had left it, because in the cases described by Col. Fremantle it would be very difficult to imagine that the mental condition of the individual could be truly explained by saying that he was incapable of expressing himself as willing or unwilling to continue to receive treatment. In other words, there would be a great many cases which could be dealt with by Clause 5 if those words were accepted. The cases which, after being admitted to the hospital voluntarily, became definitely though temporarily insane, and were very clearly able to express themselves as being unwilling to continue to receive treatment, could not, it seemed to him, come under Clause 5. As the Bill stood at present, with the new wording which the Minister had put into it, cases which became temporarily insane and desired to get out had to be certified after a month. He could conceive many people suffering from temporary insanity which one felt quite sure would come right, yet who were far from being able to express themselves as willing or unwilling to continue to receive treatment.

Sir BOYD MERRIMAN said he believed there was a quite simple explanation of the difficulty. They had to bear in mind all through, that assuming every case was a case of mental disorder, if through that disorder a man definitely refused to be treated he was to be certified. There was no escape from that. They were discussing here the length of time during which a man might be detained after he had become incapable of voluntarily continuing his treatment. If steps were taken to keep him under treatment he must be dealt with under Clause 5, or by certification. He agreed with the Minister that they must stick to the period of one month in order not to raise the question of the liberty of the subject.

Lieut.-Col. FREMANTLE withdrew his amendment.

Suggested Amendments.

Lieut.-Col. FREMANTLE moved in Subsection (3) to leave out the words "or steps have been taken to deal with him." He said he moved the amendment on behalf of Dr. Veron Davies, who felt very strongly on this point. His hon. friend wished to leave out as much as possible the control over the patient which was provided in the first four Clauses.

Mr. GREENWOOD, in resisting the amendment, said that the effect was really to cut out the express provision that in the circumstances dealt with in the Subsection a voluntary patient should be discharged, and they left him either under the principal Act or with treatment under Clause 5.

The amendment was negatived.

Lieut.-Col. FREMANTLE moved in Subsection (3) at the end to insert the words: "Provided that any written declaration by him, if he is over sixteen years of age when he was capable of volition, desiring that in the event of his losing volition his status should for a period of six months remain unaltered, be legal and binding on all concerned." He said this was really the third effort he had made on the same point. He had tried to make out the best case for those with experience, the Medico-Psychological Society. If they would not allow patients after they had lost volition to remain without further treatment for more than one month, would they do so if while the patient was still of full volitionary power he signed a definite application stating: "in case I lose volition for a period and you think I am recoverable, I want to remain under the same conditions in the same status of treatment"?

Mr. GREENWOOD said this was a very far-reaching amendment which was going to change entirely the method by which they had treated voluntary patients hitherto. It also raised controversial issues. While the proposal might appeal to many medical men, it was a very serious thing that a person should beforehand, so to speak, sign away his liberty. The case ought to be considered on its merits when the patient arrived at such a state that he was incapable of looking after himself. He hoped that the hon Member wound not press his amendment.

Lieut.-Col. FREMANTLE said most clearly the interests of all those who had asked him to move this amendment was to get the Bill through, and obviously if it did not commend itself to the Minister and the Committee in general it was not likely to get through the House. But the point having been raised it could be raised again later on some years hence in connection with an amending Bill. He asked leave to withdraw the amendment.

The amendment was withdrawn.

Dr. VERNON DAVIES moved in Subsection (4), after the word "such" to insert the words: "or fail to remove such person from the institution, hospital, home, or place when so requested in writing by the person in charge." He said he thought the new words would strengthen the Bill. There might be careless and incompetent guardians not very much interested in the case of a minor once they had got the patient under treatment.

Mr. GREENWOOD said he was not sure that the words would strengthen the Clause. He did *not* think that they added anything of value, but on the other hand, if they might be open to misunderstanding and all that could be brought within these words would be found in the word "duty" in the Subsection. He could not accept the amendment.

The amendment was negatived.

Mr. KINLEY moved an amendment to Subsection (4) to provide that the local authority should be consulted by the Board of Control in cases where a minor ceased to have a parent or guardian, or where the parent or guardian was incapable of performing, or refused or persistently neglected to perform, their duty.

Mr. GREENWOOD said the effective coordination desired by Mr. Kinley could be secured without this amendment and he imagined that the amendment might make it very difficult in many cases to secure any arrangements at all. One aspect of the Board of Control was that of an independent safeguard of persons who were in these institutions. If they were compelled to act in agreement with local authorities that immediately destroyed one of their important functions. This proposal would not work administratively.

Lieut.-Col. **Fremantle** said he sympathised with the object of the hon. Member, who moved the amendment, but he agreed with the Minister that it would be inadvisable to put the amendment into the Bill, because they were certain that the Board of Control would, whenever required, wish to be in touch with the local authorities and to make use of their machinery.

The amendment was negatived.

Penalty for Default.

Mr. **Kinley** moved to leave out Subsection (5), which imposes a penalty not exceeding £5 on any person who fails to give any notice required under the clause for each day or part of a day during which the default continues. He said an offence, however serious, could not be dealt with except by a penalty not exceeding £5. The punishment, if it was to fit the crime, should not be limited to that figure.

Mr. **Greenwood** pointed out that the effect of the amendment would be not that somebody would receive unlimited damages, but that no one could be punished. If they were to administer the Act at all, those responsible for giving notice, whether it be of the reception or of the death of a patient, must be under some penalty if they did not carry out their duties.

Sir **Boyd Merriman** said it should be made perfectly clear one way or the other whether the penalty was intended to cover Subsection (4) as well as Subsections (1) and (2). He suggested that they should insert words to the effect that a person should be liable if he failed to give any notice required under Subsection (1) and Subsection (2) of the Clause. That would put the matter beyond doubt.

Lieut.-Col. **Fremantle** said he had moved a former amendment seeking to establish the status of the medical superintendents by putting it clearly in writing that they should have definite authority to admit, discharge, etc., patients. That was refused by the Minister of Health because he said it must be left to the local authority. Surely the local authority who could give the necessary powers to their officials could presumably impose the necessary penalties? Why was it necessary to impose the penalties in the Bill and not trust the local authorities to deal with their own officers? Surely this was a retrogressive and inconsistent principle which had been too often adopted in respect of technical advisers. The reason probably was that this had always been done, and because it gave a feeling of security to the public. The medical superintendents themselves accepted that position, because public opinion was so timorous, but he hoped it would not be registered definitely that they were weighted down in that way.

Mr. **Greenwood** said local authorities did not feel insulted by this procedure, as it had been adopted before. Taking into consideration the number of private institutions quite clearly they ought to have some safeguard in the form of a penalty which would keep people up to their responsibilities.

Mr. **Kinley**'s amendment to delete the Subsection having been negatived, it was agreed, on the motion of Sir Boyd Merriman, to limit the penalty to failure to give notice required under Subsection (1) and Subsection (2) of the clause.

The clause as amended was added to the Bill.

Visitation of Voluntary Boarders.

On Clause 3, Mr. **Richard Russell** moved, in Subsection (1), to leave out the words "at any time visit a person received as a voluntary boarder under Section 1 of this Act or under the provisions of any local Act," and to insert instead: "at the request of any person received as a voluntary boarder under Section 1 of this Act, or under the provisions of any local Act, visit such person." He said the patients who submitted themselves for voluntary treatment, when they entered an institution, might be inspected the day after by a lunacy Commissioner, who might immediately certify them under the principal Act. That would be a fatal thing to happen. Nothing more disastrous to voluntary treatment could happen in any district.

Mr. **Greenwood** said he could not accept the amendment as it was based on a misapprehension. The idea that the Board of Control went about certifying people was, of course, without any foundation. What was being asked for was that no voluntary boarder should ever be visited by the Board of Control, except at the patient's request. They were told that this was being done for the protection of the patient, but such a proposal might very well be detrimental to his interests. For the general protection of persons in this category it was essential to keep independent power of inspection by the Board of Control.

Sir **Boyd Merriman** said the point of substance which he thought emerged from this discussion was whether there was any real safeguard in the Clause at all. If there were only to be five Commissioners would there ever be any real probability that Commissioners would visit voluntary patients with sufficient frequency to make their visits of any real effect for the purposes of the Bill? Though he quite understood that they could not possibly make it compulsory, the Committee would have very seriously to face later on whether there should not be more Commissioners so that visiting in this and other respects might be more effective.

Mr. **Greenwood** said it was true that there were five members of the Board, but it was part of the scheme to have a considerable staff of Visiting Commissioners. The actual visitation, therefore, was not confined to the Board of Control.

Lieut.-Col. **Fremantle** said the matter was not at all clear. It was true that Clause 11 provided for Commissioners other than the Board of Control. Those were the present Commissioners which composed the Board, 13 in number. He thought that there were to be nine of them left after this process of hari-kari, of whom five were to be members of the Board of Control, and the others senior Commissioners. Those who were being turned off the Board would be available to make visits, and he agreed that they needed people of that status for this purpose. But no provision was made in Clause 11 to replace the excellent men and women who were being turned off the Board of Control. When they died it was proposed that they should be replaced by assistant Commissioners and inspectors. He hoped that the Government would remedy this flaw in the Bill.

The amendment was negatived.

Clause 3 as amended was added to the Bill.

The Committee adjourned.

On Tuesday, March 11th, The Mental Treatment Bill was further considered by Standing Committee A of the House of Commons. Mr. Cecil Wilson was in the chair.

Power to Lodge Relatives and Friends of Boarders.

On Clause 4, Dr. **Vernon Davies** moved an amendment to provide that relatives or friends of patients might be lodged in any institution, or in any hospital, nursing home, or single care approved for this purpose by the Board of Control.

Miss **Susan Lawrence** (Parliamentary Secretary to the Ministry of Health) said that this clause was inserted in order to keep alive Clause 229 of the Lunacy Act. It was not desirable that this provision for lodging friends or relatives of patients should be extended to other institutions that registered hospitals or licensed houses. It had never been the practice to allocate accommodation which was reserved for patients in these other institutions, and the local authorities did not desire this extension. They did not want to make their asylums into great hotels.

Dr. **Morris-Jones** said he hoped the amendment would not be accepted. It might make it impossible to run the hospitals at all.

Dr. **Vernon Davies** pointed out that his amendment was permissive. It did not compel the proprietor of an institution to take in friends or relatives of patients if he had no room for them.

Replying to further questions, Miss **Susan Lawrence** explained that the clause as drafted did not include public institutions. It reproduced Clause 229 of the Lunacy Act in reference to licensed houses, and Section 230 as it had been interpreted in relation to registered hospitals. It also brought the law into conformity with the new provisions which dealt with three instead of two classes of patients.

The amendment was negatived.

Standard of Accommodation for Relations and Friends.

Lieut.-Col. **Fremantle** moved an amendment to enable friends or relatives to be lodged in accommodation which was of a lower standard than was required for the patients themselves. He said that a fairly high standard was required for patients, but there seemed no reason why other accommodation should not be used for patients' relatives.

Miss **Susan Lawrence** said that she hardly thought that the amendment was necessary. They must be strict in these matters, and they did not want boarders taken in beyond the number for which the house was licensed. The Royal Commission was divided on the question of licensed houses, and it was desired to leave them alone as far as possible.

Dr. **Morris-Jones** said that private licensed houses in this country could not extend the number of their beds beyond that allowed under the Lunacy Act of 1890. No proprietor of one of these houses would be likely to encourage friends or relatives to occupy the limited amount of accommodation which they had at their disposal.

Sir **Boyd Merriman** said that he thought that the Parliamentary Secretary was treating the matter rather too lightly. It was not to be dismissed merely by saying that by the milk produced or by the condition of the cow; and if this product continued to conform to the required standard, why had he issued an order restricting the movement of such animals if the owners, knowing their responsibilities, wished to do so; and (2) if the Minister had any evidence proving that cows exhibited at agricultural shows had become affected with tubercle at such shows; and if so, if he would lay such evidence before the House in a White Paper.—Miss Susan Lawrence (Parliamentary Secretary to the Ministry of Health) replied: The only satisfactory test for tubercle bacillus in milk is one which takes several weeks to carry out, and it is therefore necessary, in order to obtain the maximum possible safeguard againt the presence of tuberculosis in the milk in question, to lay down conditions as to the testing of the cattle and their isolation from untested animals. When a cow is found to be tuberculous it is rarely possible to determine how she has become infected, but my right hon. friend is advised that the association of tested with untested animals at a show involves a risk of infection which he would not be justified in taking in the interests of the consumers to whom he is, in effect, guaranteeing the milk as being of the highest possible purity.

Paupers and Vaccination.

Mr. Carter asked the Minister of Health whether he was aware that on Feb. 20th over 400 pauper inmates of the St. Pancras workhouse were vaccinated without being asked for their consent; that the majority of these people believed that the reason for stripping to the waist was for examination purposes only and had no idea that it was for vaccination until they were actually vaccinated; that the few men who successfully resisted this attempt to vaccinate them had their leave stopped; that no objection was raised to the men taking their discharge but only to their having leave; that Mr. L. L. Ross left the house on Feb. 22nd and returned at 7 P.M. with a new order of admission, and was told at the receiving ward that he must either agree to be vaccinated or go outside; that he refused to be vaccinated and demanded an order from the master in writing that vaccination was compulsory before he would agree to leave; that after an interview with the Assistant Master Ross was admitted 60 minutes after his arrival; that two men were refused admission on Feb. 21st at 5.30 P.M. after presenting their orders; and whether he would point out to the St. Pancras workhouse authorities that they had no right to make vaccination a condition of admission to the workhouse.—Mr. Greenwood replied: On Feb. 20th a male inmate was found to have been suffering from small-pox for three or four days and since he had been in contact freely with other inmates it was considered advisable to examine medically all the men in the institution. Opportunity was taken of advising the men to be vaccinated, but it was made clear that any who objected were at liberty to refuse. A number of men in fact refused, but no leave has been stopped on this account. As regards Mr. Ross, the facts are substantially as stated; the delay in readmitting him was due to a misunderstanding which was rectified as soon as it was brought to the notice of the Assistant Master, and steps have been taken to prevent a recurrence of the difficulty. There is no record of two men being refused admission on Feb. 21st. The duty of a poor-law authority to relieve destitution would not be affected by a refusal of the applicant to be vaccinated, but in certain circumstances it might be quite proper that relief should not be given in a particular institution.

Patients' Comfort in Poor Law Hospitals.

Dr. Hastings asked the Minister of Health whether he would take steps, in the case of Poor Law hospitals, to stop the practice of awaking patients at five o'clock in the morning for the purpose of ablutions, when these could be carried out at a more reasonable hour without interfering with their sleep.—Mr. Greenwood replied: I am anxious that everything possible should be done to study the comfort of patients and this matter is one which is constantly under consideration. I have been interested to see the steps proposed in this regard in the important hospital with which my hon. friend is connected, but as he will appreciate the subject is one in which it is difficult to make general recomdations.

Local Authorities and Birth Control.

Mr. Thurtle asked the Minister of Health the names of the 55 or more local authorities who had sent resolutions to his department in favour of local authorities being permitted to give birth-control information to married women who desired it.—Mr. Greenwood replied: I am sending the list to my hon. friend.

Silicosis.

Mr. Rennie Smith asked the Home Secretary if, following the recent Report on the conditions of silicosis, further legislation was being prepared, and when the Bill would be presented to the House.—Mr. Clynes replied: Yes, Sir. A Bill is being prepared and while I cannot pledge the Government I hope that it may be presented to Parliament before the end of the present month.

Mr. Rennie Smith asked the Home Secretary if he could give particulars of the committee appointed by the Medical Research Council further to investigate pulmonary silicosis, and other pulmonary conditions arising from industrial processes; and if he could indicate the scope of the inquiry.—Mr. Clynes replied: The appointment of this Committee and the scope of their inquiry were announced in the Press of Feb. 22nd. The Committee will advise on the further investigation of pulmonary silicosis and of other pulmonary conditions associated with the inhalation of dusts arising from industrial processes. It will be their duty to survey the whole field and to advise the Council on new lines of inquiry that may be profitably pursued, and they will assist in the supervision of such investigations as it may be decided to initiate or support. The work will be directed particularly towards obtaining, in coöperation with the Factory Department, more accurate knowledge of the causes and diagnosis of silicosis and of other industrial pulmonary disorders.

Supply of Radium.

Lieut.-Commander Kenworthy asked the Minister of Health whether any progress had been made in obtaining supplies of radium independently of the present foreign monopoly, and especially from mines and workings within the Empire; and what steps were being taken to this end.—Mr. Greenwood replied: The primary objective is to increase the amount of radium at present available for use in this country and the Radium Trust has thought it best with that object to have recourse to the existing sources of supply, including such supply as is available in this country.

Approved Societies' Reserve Funds.

Dr. Morris-Jones asked the Minister of Health the total amount of reserve funds possessed by approved societies under the National Health Insurance Acts as at Dec. 31st, 1929.—Mr. Greenwood replied: The total amount of funds of approved societies under the National Health Insurance Acts in Great Britain at the latest date for which particulars are available, viz., Dec. 31st, 1928, was in round figures as follows:—

1. Sums standing to the credit of approved societies in the National Health Insurance Funds, including amounts in the Investment Account..	£59,000,000
2. Sums invested by or on behalf of approved societies	55,000,000
3. Cash in hands of approved societies	1,500,000
Total	£115,500,000

Apart from the foregoing, there are also certain book credits called reserve values, created under those provisions of the original National Insurance Act, and subsequent enactments, which are now embodied in Section 66 of the National Health Insurance Act, 1924. These book credits will in due course be converted into cash by the operation of the sinking fund set up for the purpose. (See Section 67 of the National Health Insurance Act, 1924.) The amount of reserve values credited to approved societies in Great Britain and outstanding at Dec. 31st, 1928, was in round figures £47,500,000.

Sale of Reconstituted Milk.

Mr. Everard asked the Minister of Health, whether he was aware that at a recent food and cookery exhibition at Olympia, London, reconstituted milk was supplied to members of the public, and that a firm of manufacturers of emulsifying machines had advertised the claim that milk and cream made on their stand was supplied to all the demonstration and competition theatres at that exhibition; and whether, in view of the extended sale of emulsifying machines, he would take prompt steps to remind all food and drugs authorities that the sale of reconstituted milk was illegal.—Mr. Greenwood replied: I have received information to the effect of the first part of the question. The Food and Drugs Authorities are already aware of the statutory provision prohibiting the sale of reconstituted milk as milk, and on the information at present before me I do not think it necessary to address any special communication to them on the subject.

Factory Inspectorate.

Mr. Kelly asked the Home Secretary whether there had been any increase in the number of factory inspectors during the last year; and whether any further increase was proposed.—Mr. Clynes replied: No addition was made last year to the total strength of the inspecting staff. As regards the future, my hon. friend will no doubt have seen the announcement in the newspapers of the important changes which the Government have decided to make in the strength and organisation of the Factory Inspectorate. These include increases (to be spread over a period of five years) both in the general inspection staff and in the technical branches (medical, engineering and electrical). The general inspection staff attached to the inspection Divisions and Districts will be raised in number from 180 to 243. The technical branches will also be substantially increased, the medical staff from 5 to 8; the electrical staff from 5 to 12; and the engineering staff from 6 to 10. During the year 1930–31 it is proposed to appoint 16 additional inspectors to the divisional and district staff, making, with seven vacancies in the existing inspectorate, a total of 22 new inspectors to be appointed this year. In the technical branches two medical, two engineering and four electrical inspectors will be added.

TUESDAY, MARCH 11TH.

Doctors and Excessive Prescribing.

Mr. SORENSEN asked the Minister of Health whether he was aware that penalties were imposed on doctors recently for excessive prescribing; whether he was aware of the dissatisfaction that existed at this limitation of the purpose of health insurance; and whether he intended to take action that would remedy the situation.—Miss LAWRENCE replied: My right hon. friend gathers from the terms of my hon. friend's question that he is not aware that power to withhold remuneration from insurance doctors on account of excessive prescribing has existed and has been exercised since medical benefit first came into operation in 1913. No limitation of the scope of medical benefit is involved, and the answer to the third part of the question is therefore in the negative.

Sickness and Disablement Benefits.

Mr. RHYS DAVIES asked the Minister of Health if his attention had been called to the distress caused among those insured persons whose disablement benefit had recently been reduced under the provisions of the National Health Insurance Act, 1928; and, if so, if he would inquire into the matter with a view, if possible, to a return to the status quo in this connexion; and if he could state approximately the number of insured persons whose disablement benefit had recently been reduced consequent upon the operations of the provisions of the National Health Insurance Act, 1928.—Miss LAWRENCE (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is aware that there has been some misapprehension with regard to the reduction in the standard rates of sickness and disablement benefits payable to insured persons after the lapse of a long period without the payment of any contributions. No statistics are available as to the number of persons who are subject to such reduction, but as the payment of a single contribution for any week after June, 1928, would have been sufficient to prevent the reduction, my right hon. friend does not think that there can be many cases of the kind. The great majority of such cases would be those of persons who have paid no contributions for many years and who would, but for a special regulation which my right hon. friend recently made, have ceased to be insured and entitled to any benefits at the end of 1929. My right hon. friend is afraid that it would be very difficult to justify any further concession to these people at the cost of the benefit funds of approved societies.

Industrial Health Research Board.

Mr. MANDER asked the Secretary of State for War if he could give the results of the work carried out at the Beachley Technical School on behalf of the Industrial Health Research Board by the National Institute of Industrial Psychology in connexion with the War Office; and if he proposed to develop the matter further.—Mr. T. SHAW replied: Investigations have been undertaken with the assistance of the National Institute of Industrial Psychology to see what would be the best method of allocating to a trade boys entering the Army Technical School (Boys) at Chepstow and elsewhere as apprentice tradesmen. These investigations are still proceeding.

AN ENLARGED COTTAGE HOSPITAL.—Neston (Cheshire) and District War Memorial Cottage Hospital has been enlarged by the building of two new wards and other additions, which were recently opened by Lady Leverhulme.

MEMORIAL TO LORD HAMBLEDEN.—A bust of the late Lord Hambleden has been erected in the north-east corner of Lincoln's Inn-fields. He was for 14 years vice-chairman and for 20 years chairman of King's College Hospital, for nine years chairman of the British Hospitals Association, and one of the founders and chairman of the Hospital Saving Association.

Obituary.

HORACE STANSFIELD COLLIER, F.R.C.S.,

LATE SURGEON TO ST. MARY'S HOSPITAL.

WE regret to announce the death of Mr. Stansfield Collier, which occurred at Teynham, Kent, on Feb. 26th, after prolonged illness.

Horace Stansfield Collier was the elder son of Dr. Alfred H. Collier of Cranford, and received his medical education at St. Mary's Hospital, taking the double English qualifications in 1888, and proceeding to the F.R.C.S. in 1890. At the hospital he held the usual junior appointments, and in 1897 was elected assistant surgeon. Previous to that appointment he had been a resident at the London Fever Hospital, demonstrator of anatomy at St. Mary's Hospital, and assistant surgeon to Paddington Green Children's Hospital, while in 1898 he was elected surgeon to the Great Ormond-street Children's Hospital. The direction of his clinical work and surgical interests was early indicated, and during the whole of his long connexion with St. Mary's Hospital and with Great Ormond-street he preserved the same attachment to surgical pædiatrics.

We owe the following estimate of Stansfield Collier as colleague and teacher to Sir William Willcox:—

Horace Stansfield Collier will be remembered with affection and gratitude by many of his contemporaries at St. Mary's Hospital, and at the Hospital for Sick Children, Great Ormond-street. He was a student of St. Mary's Hospital, and, before qualifying, decided upon surgery for his future career. The enthusiasm and energy displayed in his work were remarkable, and it is feared were the cause of his early breakdown in health at a time when he had risen to a high position in the surgical world of this country. He was demonstrator of anatomy at St. Mary's Hospital from 1894 to 1898, and surgical tutor from 1897 to 1902. In 1897 he was elected to the staff of St. Mary's Hospital as assistant surgeon, and, shortly after this, was appointed to the surgical staff of the Great Ormond-street Hospital. He did a colossal amount of surgery during the period 1897–1911 and completely overtaxed a constitution that was none too strong. His health gave way in 1911, so as to necessitate his retirement from hospital practice.

Stansfield Collier was a man of lovable disposition and attractive personality. He gathered round him a host of friends amongst his colleagues, his students and the practitioners with whom he became associated. His generous disposition always made him thoughtful of the future careers of those junior to him, whatever their professional bent, and he spared no effort to encourage them in their early struggles. He was an able and attractive teacher, and was held in the highest esteem by the large number of students who attended his lectures and tutorial classes in surgery. There are many occupying high positions in the medical profession to-day whose successful careers were largely due to the helping hand extended to them by Stansfield Collier. As a surgeon the brilliancy of his diagnosis and operative skill soon made him known far outside the confines of the hospitals with which he was associated and he speedily acquired a very large practice; indeed his services became in great demand all over England, for he was seen to be a man of great originality, both in operative technique and in scientific after-treatment of cases. As, however desperate the situation might be, he never gave up hope, on many occasions remarkable recoveries resulted in apparently hopeless cases under his care. One example may be mentioned—a gymnastic instructor in the army fell in the course of his exercises and fractured the sixth and seventh cervical vertebræ. He lay completely paralysed for some months. Collier performed laminectomy, removed the broken fragments of bone pressing on the cord, and the patient made a complete recovery, Wolverhampton Eye Infirmary.—All the figures for last year's work show an increase. The new patients totalled 14,230. There were 7030 accident cases, as against 4580 ten years ago. A new ultra-violet ray department has been provided.

Radium Therapy in Cancer.—Dr. J. Murdoch, Chief Medical Officer of the Department of Radiology and Radium Therapy at the Brugmann Hospital, Brussels, will lecture on this subject at the University of Sheffield on Tuesday, May 6th. This will be the third of a series of lectures arranged by the University in coöperation with the Yorkshire branch of the British Empire Cancer Campaign. It will be open to all medical practitioners, but those who wish to come from outside areas are asked to send their names to the secretary of the Clinical Studies Committee of the University.

London School of Medicine for Women.—On Friday evening, March 7th, Lady Barrett held a reception at the London School of Medicine for Women in Hunter-street, W.C., to welcome Dame Janet Campbell on her return from Australia. A large number of guests joined in the welcome, and took an opportunity of inspecting the medical school, where various popular exhibits were put out. During the evening Prof. Ainsworth Davis demonstrated a film showing the growth of tissues to big audiences, while an interesting musical programme was rendered by Mr. Hugh Mackay, Mr. Phelps, and Miss Sheelah Field. Mr. Mackay sang old ballads, traditional in Scottish villages, and illustrative of legend, scenery, and especially farm labour; these were well suited in their accompaniments, Miss Field as harpist being very successful.

Public Assistance Hospital Arrangements.—At Darlington the two senior women members of the Board of Guardians have been coöpted as members of the Public Assistance Committee, which otherwise consists entirely of members of the Town Council. Feetham's Infirmary is to be renamed "Darlington Municipal Hospital."—In January the Wiltshire County Council found that there were 350 empty beds in various public institutions in the county, and it is proposed to obtain space for mental defectives and increased hospital accommodation by rearranging the uses to which these institutions have been put.—At Newcastle-on-Tyne it is proposed to transfer tuberculous patients from Wingrove Hospital to the phthisis pavilions at Walkergate Isolation Hospital or to Barrasford Sanatorium. Mental defectives will probably be removed from Wingrove to Shotley Bridge Colony when they are certified as suitable for treatment in that manner.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
Tuesday, March 18th.—5.30 p.m., Ballot for election to the Fellowship. 8 p.m., Pathology. Election of Officers and Council. Communications: W. W. C. Topley: Antibodies in Rabbits. Joan Taylor and H. D. Wright: Hæmolytic Streptococci in the Normal Vagina. G. R. Cameron and B. T. Mayes: The Effect of Tying the Hepatic Artery. Demonstration: J. W. Orr: Primary Carcinoma of the Liver in a Case *of Hæmochromatosis*.
Thursday.—5 p.m., Dermatology and Medicine (Cases at 4 p.m.). Special Discussion on The Therapeutic Value of Gold Compounds, Sanocrysin, &c. Openers: Prof. Lyle Cummins and Dr. A. C. Roxburgh.
Friday.—5 p.m., Balneology and Climatology. Discussion on The Influence of Sunlight and Other Climatic Factors in Health and Rheumatic Diseases. Opener: Dr. Charles W. Buckley. 8 p.m., Obstetrics and Gynæcology. Short Communication: Dr. J. Estcourt Hughes: A Case of Hydatidiform Mole with Multiple Syncytial Infarction of the Lungs. Papers: Dr. Arthur E. Giles: The Influence of Hysteropexy on Subsequent Pregnancy and of Pregnancy on a Previous Hysteropexy. Prof. W. Fletcher Shaw: The Treatment of Prolapsus Uteri. 8.30 p.m., Electro-Therapeutics. Paper: Dr. J. M. Woodburn Morison: Diaphragmatic Hernia.

ROYAL INSTITUTION, 21, Albemarle-street, W.
Tuesday, March 18th.—5.15 p.m., Dr. Charles Singer: Science of the Renaissance.
Thursday.—5.15 p.m., Mr. J. B. S. Haldane: Some Problems of Genetics.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.
Thursday, March 20th.—8.15 p.m. (at the Royal Army Medical College, Grosvenor-road, Millbank), the following amongst others will give Demonstrations: Dr. S. Adler, Sir Aldo Castellani, Colonel A. C. H. Gray, Dr. C. A. Hoare, Lieut.-Colonel S. P. James, Dr. William James, Mr. C. MacHattie and Major C. R. Chadwick, Mr. J. F. Marshall.

LONDON CLINICAL SOCIETY.
Tuesday, March 18th.—8.30 p.m. (at the London Temperance Hospital), Clinical Evening. Cases.

CHELSEA CLINICAL SOCIETY.
Tuesday, March 18th.—8.30 p.m., Dinner at the Hotel Rembrandt, Thurloe-place, S.W., followed by a discussion on Micturition. Openers: Mr. J. Everidge and Sir Thomas Carey Evans.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.
Wednesday, March 19th.—7.30 p.m., Mr. Joseph E. Barnard, F.R.S.: Presidential Address on Resolution and Visibility in Medical Microscopy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
Tuesday, March 18th.—5 p.m., Dr. Donald Hunter: The Significance to Clinical Medicine of Studies in Calcium and Phosphorus Metabolism. (Last Goulstonian Lecture).
Thursday.—5 p.m., Dr. Carey F. Coombs: Syphilis of the Heart and Great Vessels. (First Lumleian Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Monday, March 17th to Saturday, March 22nd.—Medical Society Lecture Room, 11, Chandos-street, Cavendish-square, W. Tues., 4 p.m., Lecture by Dr. John Parkinson on X Ray Examination of the Heart. No fee.—Royal Westminster Ophthalmic Hospital, Broad-street, W.C. Thurs., 2.30 p.m., Demonstration by Mr. M. L. Hine. No fee.—National Hospital for Diseases of the Heart, Westmoreland-street, W. Thurs., 3 p.m., Demonstration by Dr. F. W. Price. No fee.—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. Special Post-graduate Course of Lectures and Clinical Demonstrations. Daily at 5 p.m.—London Lock Hospital, Dean-street, W. Post-graduate Course in Venereal Disease. Clinical instruction daily in the afternoons and evenings for four weeks.—Royal National Orthopædic Hospital, Great Portland-street, W. Second week of Post-graduate Course in Orthopedics occupying all day.—Further particulars from *Fellowship of Medicine.*

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Monday, March 17th.—2.30 to 5 p.m.: Medical, Surgical, and Gynæcological Clinics. Operations.
Tuesday.—2.30 to 5 p.m.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
Wednesday.—2.30 to 5 p.m.: Medical, Skin, and Eye Clinics. *Operations.*
Thursday.—11.30 a.m.: Dental Clinics. 2.30 to 5 p.m.: Medical, Surgical, Nose, Throat, and Ear Clinics. Operations.
Friday.—10.30 a.m.: Throat, Nose, and Ear Clinics. 2.30 to 5 p.m.: Surgical, Medical, and Children's Diseases. Clinics. Operations.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James Hospital, Ouseley-road, Balham, S.W.
Thursday, March 20th.—4 p.m., Dr. Maurice Davidson: Some Points in Differential Diagnosis and Treatment in Diseases of the Chest.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.
Thursday, March 20th.—9 p.m., Dr. H. G. Hodgson: Radiology.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.
Friday, March 21st.—4 p.m., Mr. Nicol Rankin: Acute Affections of the Pharynx.

ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square, W.C.
Wednesday, March 19th.—6 p.m., Mr. E. W. *Fish*: A Theoretical Review of Treatment of the Dentine.

NATIONAL HOSPITAL POST-GRADUATE COURSE, Queen-square, W.C.
Monday, March 17th.—12 noon, Dr. Greenfield: Pathology *of Nervous System.* 2 p.m., Dr. Riddoch: Out-patient Clinic. 3.30 p.m., Dr. Adie: Forms of Muscular Atrophy.
Tuesday.—2 p.m., Dr. Walshe: Out-patient Clinic. 3.30 p.m., Dr. Grainger Stewart: Acute and Subacute *Myelitis.*
Thursday.—2 p.m., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 p.m., Dr. Riddoch: Headache.
Friday.—12 noon, Dr. *Purdon* Martin: Anatomy and Physiology of Nervous System. 2 p.m., Dr. Adie: Out-patient *Clinic.* 3.30 p.m., Dr. Symonds: Disseminated Sclerosis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
Tuesday, March 18th.—4.15 p.m., Mr. C. Roberts: Carcinoma of the Rectum.
Friday.—4.15 p.m., Dr. F. R. Ferguson: Demonstration of Medical Cases.

ANCOATS HOSPITAL POST-GRADUATE COURSE, Mill-street, Manchester.
Thursday, March 20th.—4.15 p.m., Dr. N. Klotz: Affections of the Kidneys with Special Reference to Nephritis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
Friday, March 21st.—3.30 p.m. (at the Royal Infirmary), Dr. Hallam: Some Common Skin *Diseases.*

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.
Wednesday, March 19th.—4.15 p.m. (Royal Samaritan Hospital). Dr. D. Shannon: Gynæcological Cases.

Appointments.

CAMPBELL, J. M. H., M.D., B.Ch. Oxf., F.R.C.P. Lond., has been appointed Physician to Out-patients, National Hospital for Diseases of the Heart.

FRANKS, O., M.D. Brux., L.S.A., D.P.H., Deputy Medical Officer of Health for Durham County.

HANNA, MARGARET R., M.B., B.Ch., D.P.H. Belf., Assistant Medical Officer of Health, Huddersfield.

IREDELL, C. E., M.D. Lond., M.R.C.P. Lond., M.R.C.S., Physician in charge of Electro-Therapeutic Department, Freemasons Hospital and Nursing Home, Fulham-road, S.W.

LOBBAN, J. W., M.B., Ch.B. Aberd., D.P.H., Assistant Medical Officer of Health and Assistant School Medical Officer for Chester.

RIDDELL, JAMES W. G. H., M.D. Edin., F.R.C.S. Edin., Honorary Assistant Surgeon in charge of the Obstetrical and Gynæcological Department, South Devon and East Cornwall Hospital, Plymouth.

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—M.O. At rate of £110.

Aylesbury, Royal Buckinghamshire Hospital.—Res. M.O. At rate of £180.

Barbados.—Sanitation Officer. £600.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.

Birmingham and Midland Eye Hospital.—Res. Surg. O. £150.

Birmingham, Dudley-road Hospital.—Jun. Asst. M.O.'s. All at rate of £200.

Birmingham General Hospital.—Two Res. Anæsthetists. Each £120. Also three Res. H.S.'s. Each £70.

Bolton Infirmary and Dispensary.—H.S. At rate of £150.

Bridlington Borough.—M.O.H., and School M.O. £800.

Brighton, Royal Sussex County Hospital.—H.S. £150.

Bury Infirmary.—Sen. H.S. Also 3rd H.S. At rate of £250 and £150 respectively.

Burnley, Victoria Hospital.—H.P. At rate of £125.

Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. At rate of £150.

Calcutta School of Tropical Medicine.—Prof. of Path. and Bact. Rs. 850 a month.

Cambridge, Addenbrooke's Hospital.—H.P. Also Two H.S.'s. Each at rate of £130.

Charing Cross Hospital, W.C.—Asst. Physician.

Chester County Mental Hospital.—4th Asst. M.O. £350.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Connaught Hospital, Orford-road, E.—Sen. Res. M.O. At rate of £150. Also Res. H.S. and H.P. Each at rate of £100.

Dreadnought Hospital, Greenwich.—H.P. and H.S. At rate of £110.

Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.

Durham County Council.—Venereal Diseases M.O. £750.

East London Hospital for Women and Children, Shadwell, E.—Cas. O. At rate of £125.

Edinburgh Hospital for Crippled Children.—Surgeon. £1000.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Radiologist.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hertfordshire County Council, County Sanatorium, Ware Park.—Asst. M.O. £350.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. M.O. for County Branch Hospital, Tadworth, Surrey. At rate of £250.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—Two H.P.'s at rate of £150.

Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.

Hull Royal Infirmary.—H.S. Also Cas. H.S. At rate of £150 and £130 respectively.

Ipswich, East Suffolk and Ipswich Hospital.—Two H.S.'s. Each £120.

Ipswich Sanatorium.—Asst M.O. £350.

Kensington, Fulham, and Chelsea General Hospital, 194, Finborough-road, Earl's Court, S.W.—Res. Cas. M.O. At rate of £100.

Kettering Urban District Council.—Part-time M.O. for Antenatal Work.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

Liverpool, Hahnemann Hospital, Hope-street.—Res. M.O. At rate of £100.

Liverpool Open-air Hospital for Children, Leasowe.—Jun. M.O. £150.

Liverpool, Royal Southern Hospital.—H.P., H.S., and M.O. Each £60. Also Cas. O. £100.

L.C.C.—Med. Supts. for Public Health Dept. £750–£1000.

L.C.C. Public Health Department.—Temp. Asst. Aurist. 34*s.* 6*d.* per session.

London Hospital, E.—Asst. Radiologist.

London Lock Hospital, 91, Dean-street, W.—1st and 2nd H.S.'s Each at rate of £200. Also Surg. Reg. £100.

London Lock Hospital, 283, Harrow-road, W.—Surg. Reg. £100.

London Temperance Hospital, Hampstead-road, N.—Res. M.O. Also H.P. At rate of £175 and £100 respectively.

Macclesfield General Infirmary.—2nd H.S. At rate of £150.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Jun. Res. M.O. At rate of £50.

Manchester Royal Children's Hospital, Pendlebury.—Asst. Phys. £50.

Manor House Hospital, Golders Green, N.W.—H.S. At rate of £200.

Metropolitan Hospital, Kingsland-road, E.—Physician to Dept. for Diseases of Skin.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. M.O. £250.

New Zealand, Wellington General Hospital.—Radiologist. £900.

Northern Rhodesia, Roan Antelope Copper Mines, Ltd.—2nd M.O. £900–£1000.

North Riding of Yorkshire County Council.—Asst. M.O. £600.

Northwood, Middlesex, Mount Vernon Hospital.—Radiologist. £1000.

Norwich, Norfolk and Norwich Hospital.—Hon. Asst. S.

Nottingham City Infirmary.—Res. Med. Supt. £900.

Nottingham General Hospital.—2nd Cas. O. At rate of £150.

Oswestry, Shropshire Orthopædic Hospital, &c.—Two H.S.'s. Each at rate of £200.

Portsmouth, St. Mary's Hospital, Institution, and Children's Home.—3rd Asst. Res. M.O. £250.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Phys. Also Sen. H.P., Sen. H.S., and Special H.S. Each at rate of £120. Also Jun. H.P., and Two Jun. H.S.'s. Each at rate of £90.

St. Helens Hospital, Lancashire.—Res. M.O. £250.

St. Mary's Hospital, W.—Sen. and Jun. Clin. Assts. £100 and £50 respectively. Also Obstetric Registrar. £50.

Salford City.—Jun. Asst. for Venereal Diseases Centre. £500.

Salford City Infectious Diseases Hospital.—Jun. Asst. Res. M.O. £200.

Salford Royal Hospital.—H.P., Two H.S.'s, also Cas. H.S. All at rate of £125.

Sheffield Royal Infirmary.—Ophthalmic H.S. At rate of £80.

Society of Apothecaries, Water-lane, Blackfriars, S.E.—Med. Reg. £500.

Stirling District Mental Hospital, Larbert.—Jun. Asst. M.O. £300.

Stockport, Stepping Hill Hospital, &c.—Res. Asst. Med. Supt., &c. £300.

Surrey County Council.—Asst. M.O. £600.

Wakefield, Clayton Hospital.—Two H.S.'s. Each at rate of £150.

Walsall General Hospital.—Cas. H.S. At rate of £120.

Watford, Herts, Peace Memorial Hospital.—2nd Res. M.O. At rate of £150.

West Bromwich and District General Hospital.—Cas. H.S. At rate of £200.

West Bromwich, Hallam Hospital.—Res. H.S., and Res. H.P. Each £250.

West London Hospital, Hammersmith-road, W.—Hon. Asst. Surg., Hon. Med. Reg., and Hon. Obstet. Reg.

Woolwich and District War Memorial Hospital, Shooters-hill.—H.P. and H.S. Each at rate of £125.

Willesden General Hospital, N.W.—Clin. Assts. to Surgical Out-patients' Dept.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Ramsey (Hunts), Llandudno (Caernarvon), and at Rhayader (Radnor).

Births, Marriages, and Deaths.

BIRTHS.

HOBBS.—On March 9th, at 4, Downing-street, Farnham, the wife of F. B. Hobbs, M.D., M.R.C.P., of a son.

KILNER.—On March 3rd, at North Hill, Bury St. Edmunds, the wife of Dr. S. D. Kilner, of a daughter.

TOOP.—On March 3rd, at Advie, Brunswick-road, Sutton, the wife of Dr. Howard Toop, of a son.

MARRIAGES.

GAVIN—HARRIS.—On March 4th, at Christ Church, Westminster, Dr. Alexander Gordon Douglas Gavin, M.C., to Helen Mary, elder daughter of Mr. and Mrs. G. F. Harris, of St. James'-court, S.W.

HAUXWELL—REID.—On March 10th, 1930, at the Parish Church of South Clapham, London, by the Rev. W. A. Dunn, Frank Hauxwell, M.B., Ch.B., D.P.H., Medical Officer of Health, St. Helens, Lancs, eldest son of the late Rev. F. M. and Mrs. Hauxwell, Carluke, Lanarkshire, to Margaret A. Reid, M.B., Ch.B., eldest daughter of Mr. and Mrs. Reid, 4, Abbeville-road, South Clapham, London.

STRUTHERS—TOUGH.—On March 3rd, at Holy Trinity Church, Edinburgh, John William Struthers, M.B., F.R.C.S., to Theresa Anne Ross, widow of Captain J. J. Tough, R.A.M.C.

DEATHS.

GAMACK.—On March 8th, at Oriel House, Lindfield-gardens, Hampstead, Alexander Gamack, M.D., aged 96.

GIMLETTE.—On March 7th, at Sandford House, Merton-road, Southsea, George Hart Jesmond Gimlette, C.I.E., M.D., Lt.-Col., retired, Indian Medical Service.

PIPER.—On March 5th, suddenly at King's Leigh, Whitstable, Francis Parris Piper, M.B. Lond., M.R.C.S., L.R.C.P., M.O.H.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

RHEUMATISM IN INSURANCE PRACTICE.

Now armed with this rough practical classification as with a spectroscope, let us see how our observers in 1922 divided "industrial rheumatism" into its component diseases.

Perhaps we can best visualise this spectrum of industrial rheumatism in terms of attack-rates per 1000 of all ages by supposing a practitioner to have a practice consisting of 1000 insured males and 1000 insured females. Of this "population at risk" of 2000 insured persons of all ages over 16 years of age, our experience suggested that about 46·5 per cent., or 930 patients, would seek medical advice with regard to all illnesses during a year, and of these 930 patients some 55 (or 5·9 per cent.) would be treated for rheumatic diseases in the following proportions:—

TABLE IV.

Groups.	—		Insured males.		Insured females.	
Acute rheumatic.	A	Acute rheumatism ..	1	4	2	5
		Subacute " ..	3		3	
Fibrositis ..	B	Muscular rheumatism	6	19	7	11
		Lumbago	10		3	
		Sciatica or brachial neuritis	3		1	
Chronic arthritis	C	Rheumatoid arthritis	1	8	3	6
		Osteo-arthritis ..	3		2	
		Gout	3		0	
		Unclassifiable arthritis ..	1		1	
Total "rheumatic" disease ..			33*		22	
			55			

* Discrepancy due to omission of decimal points.

In the groups A and B the figures may be taken as rough attack-rates for all ages above 16 per 1000 per annum, but with the chronic group it must be remembered that as these diseases persist and require treatment for years the figures are not annual attack-rates.

So much for our spectrum of insured "rheumatic" patients. Now let us subject our total rheumatic insured invalidity (measured by *duration* of rheumatic sickness) to the same test. It will be recalled that it amounts to 14 per cent. of the total insured sickness and disablement.

The relative economic importance of each disease can be measured by the sick absence produced by that disease, expressed as a percentage of the whole sick absence due to all rheumatic diseases. For males, osteo-arthritis is easily the largest producer of sick absence, with 22 per cent. of the total; next is rheumatoid arthritis with 17 per cent.; then *muscular rheumatism* with 12 and gout with 11; lumbago comes lower than might be expected from the vast number of patients with 11 per cent.; subacute rheumatism with 10 per cent.; sciatica with 9 per cent. Unclassifiable chronic joint change diseases are responsible for 5 per cent. and acute rheumatism for only 4 per cent. of the total "rheumatic" sickness. Among the females, partly no doubt owing to the younger age distribution, the acute group is much more prominent than in the males, and causes exactly the same amount of sick absence as the non-articular manifestations group, which is considerable on account of the large amount of sickness caused in females by muscular rheumatism.

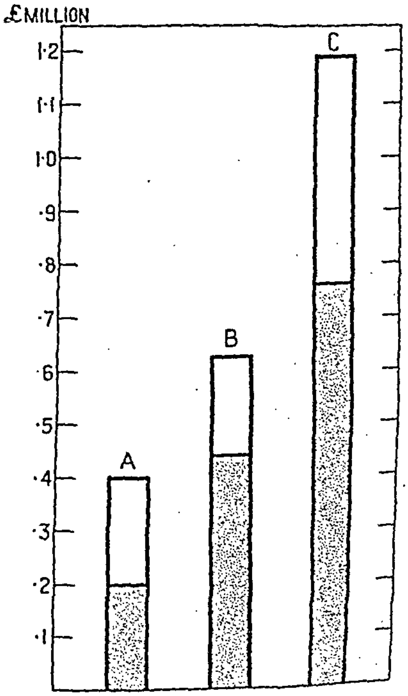
Of the separate diseases rheumatoid arthritis causes by far the most sickness, with 30 per cent. of all female rheumatic sick absence.

For both sexes together, rheumatoid arthritis and osteo-arthritis are nearly equal and far ahead of the other rheumatic diseases as producers of incapacity for work, and the proportions of sick absence produced by the acute group, the non-articular group, and the chronic joint change group respectively are nearly in the proportion 2 : 3 : 6. That is to say, chronic joint diseases cause twice as much incapacity for work as muscular rheumatism, fibrositis, lumbago, and sciatica combined, and three times as much as acute and subacute rheumatism, and when this is translated into sickness and disablement benefit we see in Fig. 3 the cost of each group in each sex to the approved societies.

Here I must point out that insured females have a much younger age distribution than insured males, in that 45·6 per cent. of insured females are between 16 and 25, and 72·7 ‡ per cent. under 35 years of age (compared with 26 per cent. and 51·6 per cent. respectively of insured males). Many women drop out of insurance on marriage.

This young age distribution of insured females makes disease statistics relating to the insured female population a much less valuable guide to the incidence of diseases upon the whole female population, for these young age-groups are relatively almost immune from the chronic rheumatic diseases. The proportion of rheumatic sick absence per person increases rapidly as age advances—a man of 55–64 having on an average 16 times as much rheumatic sick absence as one between 16–24. It is therefore essential when studying the incidence of chronic rheumatism to bear in mind the age-grouping of the population, and to examine our material *divided into* age-groups.

FIG. 3.



Estimated relative cost in benefit of the several "rheumatic" disease groups during 1928. A = Rheumatic fever (acute rheumatism) and subacute rheumatism. B = Fibrositis. C = Chronic joint stages. The stippled areas represent males.

Fig. 4 shows the male attack-rates at each age-group of the three main divisions of rheumatic diseases, and so much more common are the chronic diseases that I have put the attack-rates of the acute group in on a scale ten times larger than the two chronic groups.

It will be noticed at once the fundamental difference that the incidence of the acute group falls with increasing age, whilst the two *chronic groups* rise steeply with advancing age. The attack-rates of the various forms of fibrositis and *arthritis* have a *strong* general resemblance—a slow gradual rise in young adult life until the age of 45 is reached, when there is a sudden and pronounced upward jump. *After* 65 there is another violent upward movement due to the degenerative senile processes, but the *rise after* the age of 45 is, I think, quite clearly due to something that is not senility, but which may be probably due to endocrine changes, particularly those connected with the menopause in women. Llewellyn [19] says:—

> "The tendency of rheumatism to change its *facies* at puberty, the predilection of rheumatoid for *the* reproductive period, and of osteo-arthritis and gout for the

---

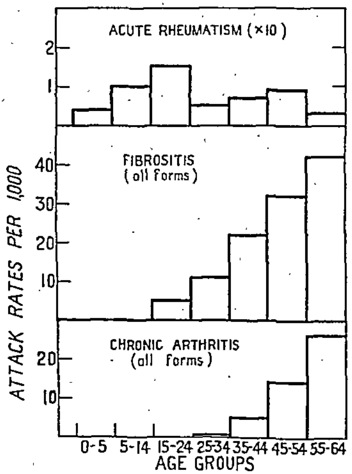
‡ Details to be found Report 235, p. 15.

menopause or pre-senile period are connected with the endocrine changes associated with those epochs."

INCIDENCE OF NON-ARTICULAR RHEUMATISM.

I shall now briefly estimate the incidence of the group of non-articular rheumatic diseases, muscular rheumatism, lumbago, and sciatica and brachial neuritis. That they are very common is a matter of common knowledge, and indeed as regards the numbers of patients they are diagnosed in nearly two-thirds of all male rheumatic patients and more than half of all female rheumatic patients.

FIG. 4.



Attack-rates from acute rheumatism (×10 scale), fibrositis and chronic arthritis among insured males of various age-groups.

Table IV. gives the approximate annual attack-rates for the four diseases found in the Ministry's inquiry for insured persons. Here we shall again see that whilst the male rates are probably fairly representative of males in England and Wales, the female rates are much less representative of the female population as a whole.

TABLE IV.—*Annual Attack-rate per 1000 Insured Persons in each Age-group.*

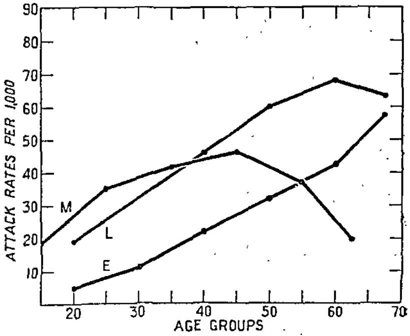
	Age-group—					All ages.
	16 to 24	25 to 34	35 to 44	45 to 54	55 to 64	
			Muscular rheumatism.			
Men ..	3	4	7	9	11	6
Women ..	4	6	10	16	18	7
			Lumbago.			
Men ..	2	6	12	18	22	10
Women ..	1	2	4	11	12	3
			Sciatica.			
Men ..	0·4	1·2	2	4	6	2·4
Women ..	0·4	0·3	1	1	5	0·6
			Brachial neuritis.			
Men ..	0·06	0·06	0·5	1	2	0·5
Women ..	0·3	0·5	1·5	4	1	0·8

Several points of interest emerge. Contrary to the opinion of many authorities who say that the disease is more (three times as) common in men, the female attack-rate for muscular rheumatism is at all ages higher than the male rate. Lumbago, however, upholds the ordinary view, the male attack-rate being far greater at all ages than the female. In the youngest group it is double, in the 25–34 group exactly three times, in the 35–44 group three times as great as the female, over middle age it is nearly twice the female attack-rate.

For sciatica and brachial neuritis together the male attack-rate is generally substantially higher than the female, the difference being entirely due to the male liability to sciatica. Later on it will be seen that in brachial neuritis the female attack-rate is much higher than the male up to 55, after which there is an increase in the male rate. It may be *observed here that for sciatica alone the ratio of male* to female cases as expressed by the attack-rates for all ages 2·4 per 1000 males to 0·6 per 1000 females, is almost exactly the 4 to 1 ratio given by Gowers,[20] which, he adds, forms a remarkable contrast to the analogous affection of the arm. For the latter, the attack-rate for males of all ages proved to stand to the female attack-rate as 0·5 to 0·8 per 1000, or very nearly as 2 is to 3.

To see how heavy an incidence these attack-rates really represent, let us suppose they apply equally to all men and women of corresponding age in England and Wales instead of applying only to insured persons.

FIG. 5.



Non-articular rheumatic diseases. Attack-rates in Moscow 1928 (M), Leipzig 1887–1907 (L), and England 1922 (E), insured males.

There are some 12,752,000 males and some 14,171,000 females in England and Wales between the ages of 15 and 65—what may be called the working half century of life. If we divide them in their age-grouping as given us by the Registrar-General, and apply the insured attack-rates, we should expect to find just a quarter of a million cases of fibrositis in each sex, cases, that is, of sufficient severity to cause the patient to consult his or her medical adviser. Dividing this fibrositis morbidity into its several parts, it represents at a rough estimate that we should expect to find yearly in all England and Wales 78,000 men and 138,000 women suffering with muscular rheumatism; 131,000 men and 72,000 women with lumbago; 35,000 male cases of sciatica and brachial neuritis, and nearly 33,000 female cases of the same. Many cases would be comparatively slight and transient.

One point which should be noted is that the sex variations are well seen in the young age-groups—i.e., before the usual age of onset of osteo-arthritis, with which sciatica, and to a somewhat less extent lumbago, are so intimately connected, and before the possible endocrine influences of the menopause can have any effect. The sex- and age-incidence represented by these attack-rates can be tested in two ways, first, by comparison with the age-incidence of previous series, such as Llewellyn's[21] for the three diseases, and secondly, by comparison with foreign attack-rates from one or two sources.

The age-incidence of the cases in the Ministry's inquiry agreed well with Llewellyn's[21] series as regards male patients when both are expressed as percentages.

German and Russian Statistics.

Llewellyn's figures do not, of course, permit of any estimation of attack-rates, as the population at risk was unknown, so that a closer comparison is with foreign statistics grouped in age-groups as are our own. Only two of these appear drawn up in forms at all comparable to our own inquiry, the monumental Leipzig statistics[10] (1887 to 1907) and the recent work of Danieschewski[11] in Moscow.

The non-articular manifestation group of diseases in our inquiry afforded an interesting comparison with the muscular rheumatism category of the Leipzig statistics, as the two categories comprise almost exactly the same set of diseases. The Leipzig category had for its main heading the term "muscular rheumatism," and included also lumbago, sciatica, and "sacral pains," so that, with the possible exception of brachial neuritis, it appears exactly to correspond with our non-articular manifestation group. The Leipzig attack-rates for this group of diseases were much higher than ours for both sexes, and at every age-group, and their days of sickness per 1000 workers in every age-group (except the two oldest age-groups, where their limitation of benefit no doubt prevents this) were much in excess of ours; but up to 45 their mean length of attack was considerably less than ours.

The comparison with the Moscow morbidity (Fig. 5) shows the English rate to be much lower for males in the young age-groups, but the female rates are very similar. For some reason I do not know, the two oldest decades evidently introduce some factor rendering the figures not comparable with either ours or those of Leipzig (Fig. 5).

The comparison with these foreign statistics is not, of course, completely fair or valid owing to great differences in the methods of collection of material, but it would, perhaps, seem fair to assume that there was considerably less non-articular rheumatic disease in England and Wales in 1922 than in Leipzig in the years from 1885 to 1903, or in Moscow in 1928. Comparison with Moscow is, however, puzzling. For men of all ages the Moscow attack-rate is 28 per 1000 compared with our rate for insured men of all ages of 19 per 1000; women of all ages in Moscow show an attack-rate of 13 per 1000 compared with one for English insured women of 11 per cent. Yet at the younger ages the Moscow experience is much higher than ours, whilst for the older groups it is much lower, quite impossibly low, it seems, on medical grounds, and there probably is some non-medical factor—e.g., some condition of insurance operating here—which renders the statistics not comparable with ours, or with Leipzig, in these two older age-groups.

Seasonal Incidence.

The seasonal incidence of fibrositis corresponds generally with that of acute rheumatism having a high winter prevalence, with peaks in November and February in Europe, the November peak not being usually present in America. There is a summer minimum usually in July. In sciatica it seems that the autumn rise occurs a good month earlier than in the other rheumatic diseases.

I shall discuss the implications of this large incidence of the various forms of fibrositis together with that of arthritis in my next lecture.

DISSEMINATED SCLEROSIS.

PATHOLOGICAL AND BIOCHEMICAL CHANGES PRODUCED BY A "VIRUS" CULTIVATED FROM THE CEREBRO-SPINAL FLUID.

BY J. A. BRAXTON HICKS, M.D., M.R.C.P. LOND.,
DIRECTOR OF PATHOLOGICAL LABORATORIES;
F. D. M. HOCKING, M.B., M.Sc. LOND., F.I.C.,
ASSISTANT PATHOLOGIST AND BIOCHEMIST: AND
SIR JAMES PURVES-STEWART, K.C.M.G., M.D.,
PHYSICIAN TO WESTMINSTER HOSPITAL.

(*From the John Burford Carlill Pathological Laboratories, Westminster Hospital.*)

SOON after the fact seemed well established by Miss Chevassut that a virus was constantly found in the cerebro-spinal fluid (C.S.F.) in disseminated sclerosis (D.S.), and that this virus was consistently absent in normal C.S. fluid and from C.S. fluids in other pathological conditions of the nervous system, it was decided to try the effect of injections of cultures of this virus into animals. At first these injections of culture were of unknown strength, but it later seemed desirable to be able to estimate the approximate strength of our cultures.

Method of Estimating Strength of Virus Suspension.

A method was devised by one of us (J. A. B. H.) as follows:—

An ordinary platinum loop is made and the loop is carefully kept, so that its volume is constant. This loop is used for removing all suspensions or drops of broth culture in the subsequent estimations. The number of drops required from this loop to make up 1 c.cm. is not a difficult problem. This is the first factor in the calculation, and it has to be worked out each time a new loop is taken into use. Slip preparations of the culture or emulsion are next made. The under slip measures 2 in. × ¾ in., and the cover slip 1½ in. × ½ in. A drop of the fluid from the standard loop is run between the cover slip and the under slip, and the two slips sealed together by means of melted paraffin wax applied around the edges by a fine camel hair brush.

One tries to so arrange one's standard loop that one drop *just* spreads out between the two slips. This is not so difficult as it may appear. Now this very thin layer between the slips represents the total volume under observation, and its proportion to 1 c.cm. is merely a matter of calculation. This is the second factor. The "slip" preparation thus made is fitted into a special carrier in order that it may be examined under the microscope.

The next factor is ascertained from the maker of the microscope, and that is the area of the field under observation as seen through an ocular fitted with a micrometer eye-piece. The area of the upper cover slip is easily estimated, and again a calculation of the ratio of this microscope field to the whole area is simple, and we have the third factor.

The average number of virus spherules per field can now be worked out by counting numerous fields and taking an average:—

Supposing—
A. = Total area of top cover slip.
AF. = Area of field under observation.
S. = Average number of "spherules" per field.
L. = Number of standard loops per c.cm.
LC. = Number of loops required to just flow under the top slip (usually one).

Then the calculation is:—

$$\frac{A.}{AF.} \times S. \times \frac{L.}{LC.} = \text{Number of virus "spherules" per c.cm.}$$

The obvious sources of error in this method at once occur to any laboratory worker, but the method is probably more accurate than some of the present methods employed to estimate the strength of bacterial emulsions. At any rate it was found possible for different workers to obtain similar results with the same virus "spherule" suspension.

This method was constantly used by Miss Chevassut in the preparation of the vaccines for patients suffering from disseminated sclerosis, but after a while we did not estimate exactly the strength of the suspension injected into animals, it being found that 5 c.cm. of a young broth culture produced no ill-effects when injected intravenously.

It was found that treatment of the culture of the virus with a 0·5 per cent. carbol-saline solution killed the virus, and this was the method of sterilising our vaccine suspensions. It was found that as regards animals, untreated cultures of the virus had no apparent immediate effect, whether given subcutaneously or intravenously, and that killed virus suspensions could be given intravenously to patients with safety. The doses used and the clinical results obtained from vaccines prepared in the laboratory are described in Sir James Purves-Stewart's paper (THE LANCET, March 15th).

Some Serological Observations. (J. A. B. H.)

It was quickly realised that fresh human serum was the ideal medium for the enrichment of the Hartley's broth used in the cultivation of the virus, and to the numerous self-sacrificing students and other workers who were bled pretty freely for the benefit of the research, we owe a debt of gratitude, for it was essential to have a good supply of human serum to obtain good results. Horse, goat, and to a slight extent rabbit's serum, though not actually inhibitory gave slower development and less luxuriant growth of the virus.

It had been ascertained (Miss Chevassut) that the serum of certain patients suffering from disseminated sclerosis subsequent to vaccine treatment proved inhibitory to the growth of the virus in culture, and for that reason some hopes were entertained of producing antibodies in animals. Thus while observations were proceeding on the effects of injections of the killed virus suspension (vaccine) into patients suffering from disseminated sclerosis attempts were made by one of us (J. A. B. H.) to ascertain if an antiserum could be prepared, and further, to see if any sort of antibody could be demonstrated by such procedure as the fixation of complement.

The rabbit was chosen for the initial experiments, and 5 c.cm. of the culture in Hartley's broth and human serum was given each time, while the control rabbit received only Hartley's broth and human serum. Some of the rabbits showed signs of collapse lasting 1–3 hours, but on the whole they were but little affected and maintained a good weight and coat throughout. They were bled at certain intervals under sterile conditions, and their serum tested against cultures of the virus.

Rabbit A received the culture every two days for five weeks, and the serum was then found to have become inhibitory to cultures of the virus. This rabbit was kept alive in order to see how long any inhibitory property lasted. Unfortunately, after it had been kept three months it developed a palsy, which at a subsequent post-mortem was found to be due to a spinal tumour, which it is hoped to describe in a subsequent paper.

Rabbit B received an injection of the culture every four days for five weeks, and the serum in this case was found to be inhibitory when tested at five weeks and again six months later.

Rabbit D received an injection every seven days for nine weeks, and was found to have become inhibitory and to remain so six months later.

Rabbit E also received an injection every seven days, and was found to be practically inhibitory after one week, and completely so in two weeks. Injections were continued in this rabbit, but it unfortunately died from acute pulmonary congestion.

Rabbit C received only Hartley's broth and serum every two days for five weeks, and no inhibitory substance developed in the serum of this control rabbit.

It thus appeared from our observations that it was possible to detect inhibitory substances in certain patients who were suffering from disseminated sclerosis, and to be able to produce inhibitory substances in rabbits in about 2–5 weeks by the injection of cultures of the virus, or in patients by the injection of vaccines.

Some of the monkeys used in the experiments to be shortly described were also bled after they had received intravenous injections, but their serum proved to be possessed of no inhibitory properties.

Some preliminary experiments were next made by one of us (J. A. B. H.) on the sera of Rabbits B and D to see if any fixation of complement occurred, but the results were negative. Later the sera of 12 patients suffering from disseminated sclerosis were similarly tested and again the results were negative.

The method used for the test was Method 4 of the Medical Research Committee's Report No. 14, with minor modifications.

Two antigens were used in these experiments, one being made up of five different cultures of the spherule, and the other from three different cultures. The antigens (broth cultures) could be used in 1/2 dilutions, and the tests were "incubated" by various ways. Being unaware as to whether the hypothetical antibody was thermo-stabile or not, the complement in the human serum was got rid of by keeping the serum for a week. The sera were divided into two halves, one series being incubated at room temperature for half an hour, followed by half an hour in the water-bath at 37° C. The other series were placed in the ice-box for 24 hours. Six sera were incubated in the ice-box for 48 hours.

All the results were negative.

Experiments on Monkeys. (By Sir J. P.-S. and J. A. B. H.)

It seemed desirable to endeavour to produce the lesions of disseminated sclerosis in animals, and monkeys were selected as most suitable for these experiments. It was determined to give cisternal and intravenous injections of broth cultures of the virus. Sir James Purves-Stewart was responsible for the intracisternal injections, while the remainder of the work was undertaken by J. A. B. H. and the laboratory staff as a whole.

It was decided to give some of the monkeys only intravenous injections, some only intracisternal and some injections of broth cultures of the virus by both routes. The intervals were chosen so that some monkeys received a single injection, while others had repeated injections of broth cultures of the virus. The injections had necessarily to be given under an anæsthetic, and the anæsthetic that disturbed the monkeys least was found to be an A.C.E. mixture. One or two of our monkeys had an anæsthetic at weekly intervals without apparently suffering any ill-effects. In only two instances did we have any anxiety after the termination of the operation for intracisternal puncture, and in most instances the monkeys were munching an apple within half an hour of the puncture being completed. The anæsthetic was given in a chamber slightly modified from the pattern employed by Prof. Voronoff in his rejuvenation experiments.[1] This permits the animal to be anæsthetised very quietly, under full observation. Indeed, they merely salivate and then topple over sleepily, when anæsthesia can be continued on a warmed table. We kept our animals wrapped up in blankets while recovering from the anæsthetic, and always in front of a fire. The monkeys never experienced the slightest respiratory trouble, though we were working through the very cold weather of early 1929.

FIG. 1.

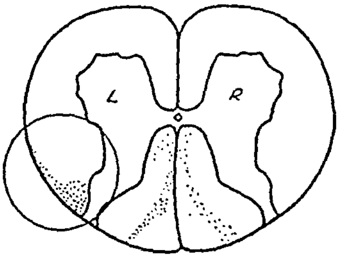

FIG. 3.

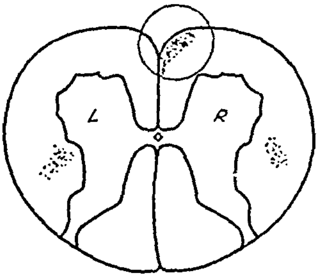

FIG. 5.

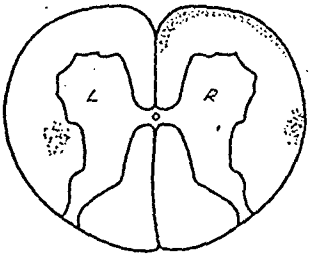

FIG. 1 (Monkey 4).—Degeneration in cervical region (Marchi method). The part outlined in a circle is seen in Fig 2.

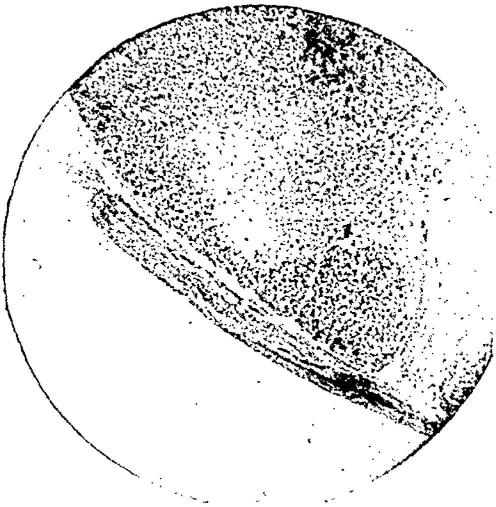
FIG. 3 (Monkey 5).—Degeneration in lumbar cord. The part outlined in a circle is seen in Fig. 4.

FIG. 5 (Monkey 5).—Degeneration in dorsal cord.

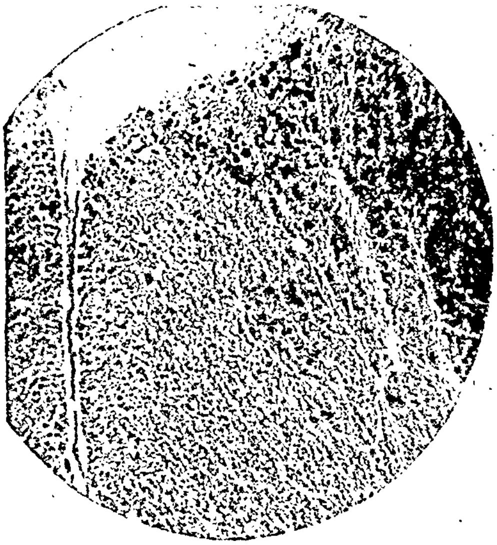
We lost one monkey during the operation of cisternal puncture, and one monkey (Monkey 7) from acute gastro-enteritis after it had remained healthy under experiment for many months. With the exception of Monkey 4 (to be described later) all the rest remained lively and in good health and coat, especially one fed on daily rations of whisky (Monkey 2). We gave this monkey whisky in an attempt to damage the antitoxic functions of the liver, since it had been found (Miss K. Chevassut) that this function was defective in patients suffering from disseminated sclerosis. However, when this animal was investigated, the liver was found histologically unaltered.

FIG. 2.



Monkey 4.—Photomicrograph of portion within circle in Fig. 1. (× 60.)

FIG. 4.



Monkey 5.—Photomicrograph of portion within circle in Fig. 3. (× 60.)

The spinal cords were examined by various methods, most of the cords being treated by Marchi and Weigert-Pal methods and embedded in celloidin. Some were also embedded in paraffin and stained by hæmatoxylin and eosin, and some also frozen and treated by Scharlach R. My senior technical assistant (Mr. F. R. Chopping) obtained some promising results from frozen sections and a modification of Marchi's method.

Below is shown a brief account of our experiments and the histological findings.

Monkey 1.—A single intravenous injection of 5 c.cm. cerebro-spinal fluid from a case of disseminated sclerosis. The cisternal fluid of the monkey was examined one month and six months later. Cultures found negative on both occasions. Eighteen months after the original injection, 5 c.cm. of a broth culture of the virus was given intravenously. Monkey killed six months after this intravenous injection. Cultures from cisternal fluid negative. Sections of the cord showed nothing abnormal.

Monkey 2.—An intracisternal injection of cerebro-spinal fluid (2 c.cm.) only. The cisternal fluid was examined one month and six months later, and cultures were found negative on both occasions. The monkey was now put on a daily ration of whisky (℥ iis. to ℥ iv.) by mouth. Combined injections by intracisternal (2 c.cm.) and intravenous (5 c.cm.) routes were given at monthly intervals on six separate occasions. After the second of these injections the cisternal fluid was examined, and cultures from it were found to be positive for the virus and remained so at every subsequent examination. Five months after the last injection the animal was killed. The cultures from the cisternal fluid were still positive for the virus. Sections of the cord showed nothing abnormal.

---

[1] Étude sur la Vieillesse et le Rajeunissement par la Greffe, Paris, 1926. (See Figs. 18 and 19.)

Monkey 3.—A single intravenous and intracisternal injection from a culture from the fluid of disseminated sclerosis was given. The cisternal fluid was examined one month and six months after and found positive for the virus on both occasions. Twelve months after the first injection the animal received a second intracisternal injection of culture, and was killed seven months later. Cultures from the cisternal fluid were negative on this occasion, though on two previous occasions they had proved positive. Bearing in mind experimental errors there also occurred to us the possibility of acquiring immunity. Sections of the cord showed nothing abnormal.

Monkey 4.—This was our most interesting animal. This monkey received a single intravenous injection of 5 c.cm. of a culture of the virus. Cultures from the cisternal fluid made at one, two, and six months intervals from this injection proved positive for the virus. About nine months after the intravenous injection a transient paresis was observed in the hind limbs. This passed off in about three weeks. The animal subsequently developed several similar attacks, each rather worse than the former until 14 months after the injection the condition became serious. The paresis had spread to the fore limbs, and was more marked on the left side than the right. The tail also was weakened, and towards the final stages the monkey could not climb on to the perch, and lay on the bottom of the cage. It took its food well, and the coat remained in good condition till it was killed to prevent further suffering. A suitable sample of cerebro-spinal fluid could not be obtained at this stage. Sections of the spinal cord stained by Marchi's method show two distinct tracts of systemic degeneration (ascending). One is situated in the left postero-median column at its junction with the postero-external, and the other is seen in the direct cerebellar tract on the left side (see Figs. 1 and 2). In some of the sections stained by hæmatoxylin and eosin there seemed to be evidence of perivascular "cuffing," but the blood-vessels themselves were unaffected. These changes were slight, but seemed to us of importance because abnormal and occurring in this monkey.

Monkey 5.—This also proved an interesting animal, since it was apparently healthy, only sections of the cord suggesting early pathological changes. This monkey received combined intracisternal and intravenous injections of broth cultures of the virus, at monthly intervals for seven months. The cisternal fluid was examined frequently and found to yield positive cultures. It was killed three months after the last injection. Sections of the spinal cord in the cervical, thoracic, and lumbar regions (Marchi method) showed well-marked and fairly compact degeneration at the periphery of the antero-medium column, together with a few scattered patches in both lateral columns (Figs. 3, 4, and 5).

Monkey 6.—Received combined intravenous and intracisternal injections of cultures of the virus and the cerebro-spinal fluid in a case of disseminated sclerosis. The cerebro-spinal fluid was examined two months and seven months later, and cultures were found positive for the virus. The animal was killed seven months after the injection. Cultures made from the cerebro-spinal fluid proved positive, but the liver and spleen were negative for the virus. Sections of the cord showed nothing of note.

Monkey 7.—This experiment was an attempt at transmission from monkey to monkey. The animal received a combined intracisternal and intravenous injections of a culture obtained from the cerebro-spinal fluid of the case Monkey 4. The spinal fluid was examined two months and four months later, and cultures proved negative. Further combined intracisternal and intravenous injections were commenced, but the animal died from an acute enteritis. The viscera were much decomposed as death occurred over the week-end and the cord proved valueless for histological examination.

The only results in any way positive as regards histological changes in the spinal cord were those found in Monkeys 4 and 5. Monkey 4 had definite clinical symptoms, but Monkey 5 had nothing apparently the matter with it when killed. The cords were removed carefully, so that precautions were taken to avoid the changes due to artefacts.

As regards Monkey 4, the question of cage paralysis must be carefully considered, in spite of the fact that all our animals were quite lively and apparently in good health and coat. The degenerations appear to be definitely systemic in character, but there does not appear to be any reference available as to the changes found in the cord in cage palsy, so that one is unable to make any comparison.

One of us (J. A. B. H.) is convinced that the best way to pursue further investigations will probably be by the injections of cultures intravenously, and by single or perhaps two large injections, rather than by repeated injections of small doses. Some of the effects of "vaccines" on human cases do suggest some possible immunity though animal experiments as far as the sera of monkeys were concerned were negative.

Summary.

1. A method has been devised for estimating the strength of the suspension of the virus isolated from disseminated sclerosis.

2. This virus is readily killed with carbol-saline, and suspensions of it can be used as experimental vaccines, and administered intravenously without harm.

3. There is some evidence that after the administration of a virus suspension to patients and to rabbits, inhibitory substances are formed in their sera. There is no similar evidence in the case of monkeys.

4. No complement-fixation phenomena can be observed in patients who have disseminated sclerosis or who have had vaccines administered. The sera of virus injected rabbits also show no complement fixation.

5. No immediate harm results from the injection of large doses of the unkilled virus, but in two monkeys certain systemic tract degenerations have been detected in the cord some ten months later. It is not claimed that these lesions are disseminated sclerosis but their presence is suggestive.

6. It seems highly probable that the best experimental results will be obtained by the intravenous route.

BIOCHEMICAL OBSERVATIONS UPON MYELIN DEGENERATION.

By F. D. M. Hocking.

As one of the characteristic lesions in disseminated sclerosis consists in a degeneration of the medullary sheath with a splitting off of unsaturated acids of the oleic acid series staining black with osmic acid, it was thought desirable to inquire whether the virus described by Miss Chevassut was capable of splitting the lipoids of nervous tissue in vitro. To this end it was decided to attempt to prepare a physically stable emulsion of brain lipoids in human serum and Hartley's broth, and to incubate this fatty medium together with a culture of the virus. It was anticipated that any action which might occur would probably be of the nature of a splitting off either of free fatty acids, or of phosphoric acid, evidence of which would be obtained by a change in the hydrogen-ion concentration of the mixture, corresponding to the amount of acid liberated.

The hydrogen electrode used was of the Rideal pattern, in conjunction with a calomel electrode of ordinary type, a potentiometer and a galvanometer. The instrument was found to be accurate and sensitive to a reading of 2 millivolts.

The lipoid material required for these observations was extracted from a fresh brain obtained post mortem from a case in which there was no possible suspicion of any central nervous disease. The whole brain was finely minced and dried by intimately mixing with three times its weight of plaster-of-Paris. The result was to produce a hard, stony mass which, after being ground to a fine powder was extracted successively with absolute alcohol, ether, acetone, and chloroform, four litres of each solvent being used. These solvents were subsequently removed from the dissolved fat by distillation under reduced pressure in a stream of dry carbon dioxide. The temperature of the heating bath was never allowed to exceed 40° C. All the extracts thus obtained were mixed together, the total yield being 64 g. of a pale yellow (almost white) coarsely crystalline, dry fat. A 2 per cent. solution of this fat was then prepared in a mixture of acetone and ether, so adjusted that no constituent of the fatty mixture remained undissolved. It was found that the whole of the lipoid material could then be brought satisfactorily into solution. When added to Hartley's broth, the fat from this solution separates out into a fine suspension which remains stable for three weeks or longer, and which, moreover, does not tend to separate even on boiling.

The preparation which yielded the optimum concentration of fat for this work proved to be an emulsion prepared by the addition of 10 c.cm. of the fat solution to 90 c.cm. of Hartley's broth, an adequate amount of human blood serum—approximately one-third of the total volume—being subsequently added after the fat solvents had been removed. The ether and acetone were removed by heating the mixture to 50° C. for 30 minutes with constant and fairly violent shaking of the fluid. This method was found to be efficient, no stream of neutral gas being required.

It was necessary first of all to find out whether or not the organism would grow in this fatty medium. Cultures were therefore made and examined daily, when it was seen that the spherules grew and multiplied in a normal manner. In the microscopical field it was easy to pick out the spherules from the highly refractile fat droplets although many of these were less than 0·2 μ in diameter.

Before proceeding to the experiment proper it was necessary for comparative purposes to perform a number of control tests with cerebro-spinal fluid and cultures from other diseases. In the first series of experiments, cerebro-spinal fluids from a number of cases of organic nervous disease other than disseminated sclerosis were incubated with Hartley's broth both alone and after the addition of the brain fat. The hydrogen-ion concentration was determined daily, and in all cases was found to remain constant within the limits of experimental error. The actual results obtained in a number of the cases is shown in Tables I. and II.

A second series of cultures was then prepared, consisting of a broth culture of the virus of disseminated sclerosis, in Hartley's broth, and blood serum only. The results showed a progressive increase in acidity during the first four to six days, followed by a gradual return to the original level; in a few cases a more alkaline reaction was ultimately attained. These results are shown in Table III.

These results at first were somewhat disconcerting as they showed a change in reaction which it was anticipated would occur only after the addition of fat. It therefore became necessary to investigate the cause of this acid formation and its subsequent neutralisation. Three sources of acid formation are possible, viz:—

1. From carbohydrates present in the broth, serum, or cerebro-spinal fluid;
2. From the neutral fats present in the blood serum added to the cultures; and
3. From the breaking down of proteins and polypeptides into simpler compounds or substances, particularly the amino-acids.

The amount of sugar present in Hartley's broth, even after the addition of serum and cerebro-spinal fluid, was found in a series of cases never to exceed 0·01 per cent., and in most cases was either far below this level or present in such minute amounts as to be impossible of detection by such tests as the formation of osazones and copper reduction. In reality a little consideration will show that any sugar originally present in the meat from which the broth has been prepared is completely destroyed during the fermentative process of manufacture. It has further been shown that sugar disappears spontaneously from normal blood serum on keeping, owing to the presence of a glycolytic enzyme. Incidentally, Miss Chevassut has previously shown[2] that a similar enzyme is also present in cerebro-spinal fluid. The serum used in all these experiments was kept for a sufficient time before use to eliminate the possibility of any sugar entering the cultures, so that carbohydrates as a source of acid formation are improbable. With regard to the suggestion made by A. I. Kendall[3] that sugars may be split off from glucoproteins, these substances are in the first place almost completely hydrolysed during the preparation of the broth, the sugar being subsequently destroyed, and they exist in only very small amounts in blood serum. As a final test, however, inoculation of a mixture of Hartley's broth and serum with cultures of *Bacillus coli* failed to produce any gas in 14 days. Finally, any acidity due to accumulation of free CO_2 has been purposely eliminated by employing a stream of pure hydrogen in the electrode.

The possibility that the increase in acidity is due to hydrolysis of neutral fats present in the broth or serum was eliminated by a direct determination of the total ethereal extract and its acid value, both before and after incubation for ten days with a broth culture of the spherule. The total ethereal extract was found to average 0·082 per cent., with a negligible acid value, so small indeed as to be incapable of accurate determination. The same was found to be the case after incubation, so that free fatty acid formation as a cause of the acidity is also highly improbable.

There remains the possibility that the observed increase in acidity may be due to a process of hydrolysis of protein and polypeptides into amino-acids, and that the subsequent neutralisation may be due to a further disintegration of these bodies whereby ammonia is liberated. That this in fact is the probable explanation of the changes observed may be inferred from the results of a determination of the amino-acid content, the hydrogen-ion concentration, and the ammonia in a number of cases, shown in Table IV.

It will be observed that there is a progressive and approximately uniform increase in the amount of amino-acids present, sufficient indeed to account for the change in reaction in the medium. We are therefore justified in assuming that the observed increase in acidity is the result of a breakdown of protein by the virus.

It is more difficult to explain the erratic results obtained for the ammonia content, particularly the decrease which occurs during the first part of the experiment, which will, of course, account for some of the acid production. That this decrease is not due to actual loss of ammonia is shown by the fact that a series of determinations of free amino ($-NH_2$) groups in the culture medium yielded practically identical

[3] Jour. Biol. Chem., 1912, xii., 215.

results both before and during the course of incubation. We must therefore tentatively infer that some process of recombination of ammonia with hydroxy-acids occurs. This may possibly be associated with some special stage in the life-history of the organism.

Having established that the virus will grow in this fatty suspension, and having obtained for comparative purposes characteristic curves of the normal changes produced as a result of its propagation, daily pH determinations were carried out on a series of cultures inoculated into the fatty emulsion. It was anticipated that there would be a gradual and progressive increase in acidity in addition to that produced as a result of protein breakdown. The actual results obtained, which are precisely opposed to those expected, are shown in Table V.

It will thus be observed that after a short period (24–48 hours), during which there is a slight tendency to increase acid formation, there is a progressive *diminution* in acidity towards an approximately constant value. In order to determine whether or not, at the level thus obtained, the virus had actually been killed off or was only inhibited in its further development, the cultures used in the above experiment were reinoculated into the fat emulsion, the daily pH values being determined as before, with the results shown in Table VI.

Many of the cultures, therefore, retained their vitality after growing for 14 days in the fat, and were still capable of reproducing the same results obtained as when first inoculated into fat.

Estimations of amino-acid production in the fatty medium, to compare with those in which no fat was used, were then undertaken for comparative purposes, and the results are shown in Table VII.

In spite of an increase in the amount of amino-acids present, there is a progressive diminution in hydrogen-ion concentration of the cultures. This cannot be accounted for by an increase in the ammonia content which is approximately the same as before. The only other likely possibility is that it is not the free fatty acids which are primarily split off from the fatty molecule, but the nitrogenous base choline. If this is so, it amply corroborates the observations of Halliburton and others that choline can be demonstrated in the cerebro-spinal fluid in lesions associated with nervous disintegration. An attempt to isolate from cultures the free base in the form of its platino-chloride has, so far, given inconclusive results, possibly because it is still bound to a larger molecule by linkages which do not involve either its amine or hydroxyl groups.

A determination of the acid value of the ethereal extract from the fatty medium, both before and after incubation with the virus, gave results which do not suggest that any splitting off of free fatty acids occurs as a result of metabolic activities on the part of the virus.

The conclusion which may legitimately be drawn from these investigations appears to be that cerebro-spinal fluids containing this particular virus exert a specific hydrolytic action not only upon proteins and their disintegration products, but also upon the fatty constituents which occur in nervous tissues. A substance is split off from the latter in vitro, which can be detected in these fluids when organic degenerations of the nervous system are present.

In conclusion, we wish to thank the various members of our technical staff for their invaluable assistance, and we mention by name Mr. F. R. Chopping, our senior technical assistant, and Messrs. W. Lewington, F. Wilson, and A. Morris.

HOSPITAL ALMONERS.—The annual report of the Institute of Hospital Almoners records a considerable increase in the number of trained almoners in the service of hospitals. The number of students in training also shows an increase.

SMALL-POX AND VACCINATION IN THE LIGHT OF MODERN KNOWLEDGE.*

BY JAMES McINTOSH, M.D. ABERD.

DIRECTOR OF THE BLAND-SUTTON INSTITUTE OF PATHOLOGY, MIDDLESEX HOSPITAL; PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON.

THE most important features of small-pox which have been noted in recent years are the changes in age incidence and in virulence of the disease and the problems which have arisen in relation to vaccination.

Change in Virulence and Age Incidence.

According to Creighton (1894) in his great classic, "The History of Epidemics in Great Britain," the earliest authenticated references in Europe to small-pox appear only in the sixteenth century. The disease was well known before this to the Arab physicians; for Rhazes's treatise, the first book on small-pox, appeared in the tenth century. But it was not till the reign of James I. that small-pox began to be recognised as a killing disease in Britain. Before this it had undoubtedly been mixed up with measles, and in Elizabethan times the word "variola" was mostly applied to measles. Up to this time small-pox had been regarded as a mild disease. Thus Whitaker wrote in the middle of the seventeenth century that small-pox was "petit" and puerile and the cure "of no moment." Willis expresses much the same view, as also does Parrott, in his "Acute Diseases of Children." Undoubtedly great attention was drawn to small-pox on the death of Queen Anne from it in 1694, and it seems to have been particularly fatal to the Stuarts, since a sister and brother of Charles II. died from it in 1660.

Small-pox, therefore, came gradually into prominence and made no dramatic outburst like plague and syphilis. *In the Stuart period, and for a long time* afterwards, it produced its chief fatality among infants and children and, as it were, only incidentally affected adults. In the severe epidemic of 1783–1800 which occurred in Glasgow and which may be said to mark the highest degree of virulence, something like 90 per cent. of the deaths were in children under 5 years of age. The highest mortality at this period was over 30 per cent. Figures up to 50 per cent. however, have been recorded in certain outbreaks.

The increase in the virulence of small-pox was quite evident early in the eighteenth century and, as a result of this, the public as well as medical science were roused to combat the ravages of the infection. Thus when the protective properties of small-pox inoculation were brought to the notice of London society in 1721 people were quite ready for its adoption. To the various steps in the evolution first of inoculation and then of vaccination I shall return later.

As time went on, and specially towards the end of the nineteenth century, a change began to be noted both in the age incidence and in the virulence of the disease. The great epidemic of small-pox of 1837–40 still chiefly affected infants as formerly, but from the epidemic of 1871–72 and onwards the chief brunt of infection has been borne by young persons and adults, rather than infants and children. The virulence of the disease as judged by the case mortality showed a definite decline by the beginning of the twentieth century.

Two Types of Small-pox.

Rajchman (1928), in his authoritative paper on the Control of Small-pox, definitely states that: "The manifestations of small-pox in recent years have been characterised by (1) a very well-marked decrease in the incidence, and (2) an almost universal decrease of the case mortality." The figures, however, have been somewhat complicated by the appearance of a very mild type of small-pox known as alastrim. This mild form is believed to have appeared in this country about 1919, and since that time the number of small-pox cases (alastrim) has increased to over 2000 per annum. The general mortality from small-pox has fallen from 11·4 in 1920 to 0·3 and 0·2 at the present moment. Outbreaks of classical small-pox, with mortalities of 30 per cent. and over, have occurred in localised areas (London, 1922; in the *Tuscania* outbreak, 1929), but always from the importation of a fresh virus from abroad.

---

* Abstract of an Address delivered before the Stourbridge and District Medical Society on Feb. 4th.

Apparently, it seems that there are two distinct types of small-pox and that they can exist side by side. They are, first, the classical or virulent form which is no longer endemic in this country and, secondly, the mild form of alastrim prevalent in South America, West Indies, South Africa, Australia, &c. Thus it may be said that these two forms breed true, for no good evidence has been brought to light to show that the mild form has ever given rise to the severe form of the disease. Yet experimental investigation mostly tends to show a very close relationship between the virus of alastrim and that of small-pox. Histologically, the lesions are identical; there are the same intracellular corpuscles † and bodies ‡ in the lesions while the serological tests (flocculation, complement-fixation, &c.) give similar results (Gordon, 1925, Ledingham, 1925). On the other hand, cross immunity experiments are not quite so definite and they suggest that there is a considerable antigenic difference between the viruses of vaccinia and alastrim. Thus cases of alastrim can often be successfully vaccinated after the attack, yet vaccination strongly protects against alastrim. Alastrim is a mild disease affecting, to a large extent, those in the lower ranks of life, especially undernourished. The question at present is whether the mild cases should be reported as alastrim and not as small-pox.

How, then, are we to explain this fluctuation in virulence? May it only be that true small-pox, like many epidemic disorders, shows these periodic changes of virulence, the meaning of which has given epidemiologists much room for thought? Whilst alastrim must be regarded as something apart Or it may be that the early accounts of small-pox, in the sixteenth century, really referred to the presence of alastrim, and that classical or virulent small-pox was introduced for the first time in the Stuart period.

The change in the age distribution of small-pox seems most likely to have been influenced chiefly by vaccination although other causes have been suggested, but it is difficult to determine to what extent other causes have been at work as well.

Vaccination.

There are three features of vaccination which I wish to discuss: (1) The nature or source of origin of the virus. (2) Vaccination as a general disease. (3) Nervous complications.

The Nature or Origin of Vaccine Virus.

The true nature, or rather the source of origin, of vaccine lymph has been a subject for discussion since the very inception of Jennerian vaccination, but I am afraid that the true nature of Jenner's inoculum can never be definitely decided now. Since his time, however, much has come to light which is rather against the fact that vaccinia virus (vaccine lymph) is really a true cow-pox. It was, of course, assumed in the Act of 1810 which prohibited variolation that the Jennerian vaccine was true cow-pox; in other words, it was a contagious disease of cattle and not a disease produced in cattle by the accidental inoculation of small-pox virus. Considerable support was given to the view that cow-pox was a spontaneous disease of cattle by the fact that it was extremely difficult to inoculate cattle with variolous material. We now know that this difficulty is more apparent than real, and arises from the insignificance of the primary lesion, and that small-pox can be transmitted to cattle, horses, and other animals.

Vaccination, as I have already indicated, undoubtedly arose out of a well-merited demand for some measure of protection against the frequency and virulence of small-pox and which had none of the disadvantages of small-pox inoculation. The first attempt at protection against small-pox was the inoculation of small-pox material, or as it is called, variolation. This was introduced into England in 1721, although the procedure had been practised in the East for some considerable time. The disease produced by inoculation was mostly of a very mild character, and this mild disease, of course, protected against small-pox. We all know that the introduction of small-pox inoculation has been accredited to Lady Mary Wortley Montagu, who had one child inoculated in Constantinople by the medical attendant (Maitland) at the British Embassy. After this had proved successful she had a second child inoculated in London. These successful results set the fashion and inoculation against small-pox became quite a rage amongst the wealthier classes, and even the Princess of Wales had two daughters inoculated. Though a few disquieting results checked the advance of inoculation for a time, by the year 1743, according to Creighton (1887), it had become quite a lucrative branch of medical practice. In 1746, institutes were opened in London for the carrying out of small-pox inoculation, as at the Middlesex County Hospital for small-pox in Windmill-street and at Bethnal Green. Many children were inoculated each year with only a few bad results. Such accidents as arose from time to time were the development of a severe form of the disease with occasional fatal results, whilst in one or two instances it was averred that infection had been spread by cases of inoculated small-pox.

The next advance in the process of inoculation was made by Sutton and was known as the Suttonian inoculation. His procedure was kept secret for a time, but its chief merit was that the virus was obtained from cases of inoculated small-pox, not from natural small-pox. In other words, this was an "arm-to-arm" inoculation of inoculated small-pox. It is said that Sutton and his assistant inoculated over 20,000 cases between 1764 and 1766, with practically no untoward results, and that in the year 1765 he made over £6000 profit. He claimed by his method that there was no danger of spreading infection.

It is thus evident that by the end of the eighteenth century inoculation against small-pox had, in general, been accepted as a salutary and safe procedure against the disease. With the idea of obtaining a still milder inoculum against small-pox, other procedures were attempted. These consisted mainly of attempts to make use of such natural diseases of animals as swine-pox, cow-pox, and horse-pox. Thus, in 1774 cow-pox was first inoculated into a human being by Benjamin Jesty, a farmer of Dorset, and in 1789 Jenner inoculated his own child of 8 months with swine-pox material. Both Jenner and Jesty were familiar with the popular belief which had existed in Gloucestershire for a long time, that people who had accidentally become infected with cow-pox were protected against small-pox. But it was not till 1796 that Jenner inoculated a healthy boy of 8 years with cow-pox material from the hand of a dairymaid, and a couple of months later, on inoculation with small-pox material, the boy was found to be immune. This was the only case mentioned in his original communication. Later, he carried out a similar experiment on another child with complete success. These apparently were all the experiments that Jenner did with regard to the actual protection of cow-pox inoculation against small-pox. But his original paper also contains particulars of ten instances where a supposed previous attack of cow-pox in dairy workers protected against exposure to small-pox infection. Crookshank, in his "History and Pathology of Vaccination" (1889), after reviewing Jenner's original paper, states "Such was the evidence

THREE NEW INSTRUMENTS FOR OBTAINING AND WORKING FASCIAL SUTURES.

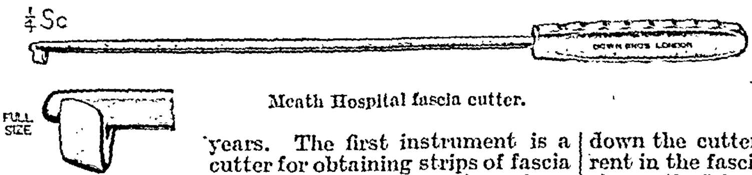
By T. J. D. LANE, M.D. Dub., D.T.M. & H.,
VISITING SURGEON, MEATH HOSPITAL AND CO. DUBLIN INFIRMARY; SURGEON, EXTERN DEPT., NATIONAL CHILDREN'S HOSPITAL, DUBLIN;

AND

T. A. AUSTIN, L.R.C.P. & S. Irel., D.T.M. & H.,
EAST AFRICAN MEDICAL SERVICE; LATE HOUSE SURGEON, MEATH HOSPITAL, ETC.

THE instruments to be described were devised at the Meath Hospital and Co. Dublin Infirmary, and have been in use in one form or other for a couple of years. The first instrument is a cutter for obtaining strips of fascia lata subcutaneously through a single small incision. The credit for first thinking of obtaining fascia lata subcutaneously and also for first very successfully putting his idea into execution belongs entirely to our colleague, Mr. Henry Stokes.

FIG. 1.



Meath Hospital fascia cutter.

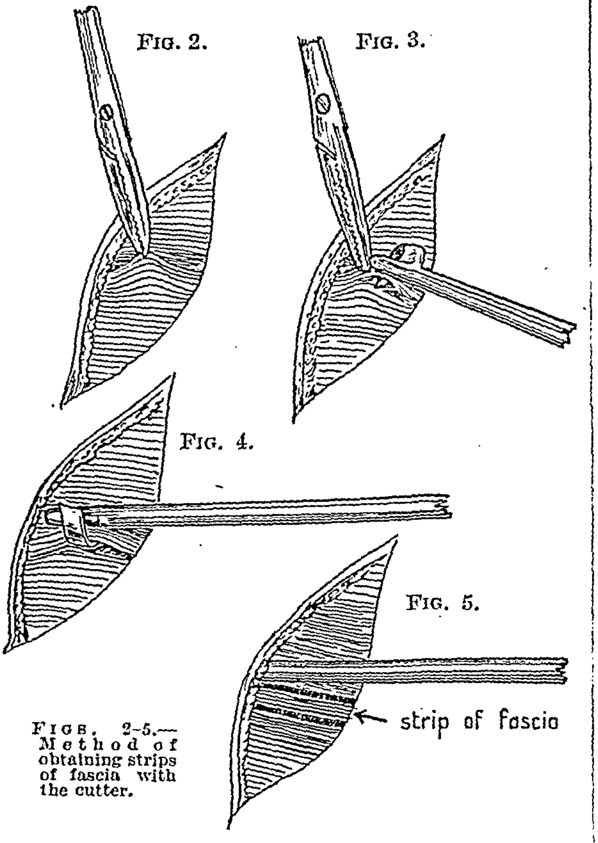


FIG. 2.

FIG. 3.

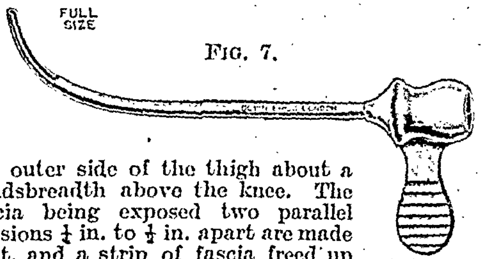
FIG. 4.

FIG. 5.

FIGS. 2–5.—Method of obtaining strips of fascia with the cutter.

Stokes's instrument consists of a short tube about ⅓ in. long by ¼ in. in diameter, mounted on a steel rod 12 in. long, which is provided with a handle at its other end. The tube is fixed parallel to the rod and is provided with a cutting edge at its distal end. To obtain the fascia lata, a short incision is made on the outer side of the thigh about a handsbreadth above the knee. The fascia being exposed two parallel incisions ¼ in. to ⅓ in. apart are made in it, and a strip of fascia freed up and snipped across at its distal end. This strip is now threaded through the tubular cutter. With the free end of the strip held by an artery forceps, the cutter is pushed subcutaneously straight up the thigh in the line of the fibres of the fascia lata. The cutter is pushed up as far as possible and is then held steady, and a small incision is made down on it. The fascia lata is exposed and the proximal end of the strip is cut free. Other strips as desired may now be cut by pulling down the cutter and starting the process again. The rent in the fascia is, of course, not sutured, and though the method has been in use for a couple of years no ill-effects have followed this omission. This instrument is made by Messrs. Smith and Shepherd, Stephen's Green, Dublin, Ireland.

FIG. 7.

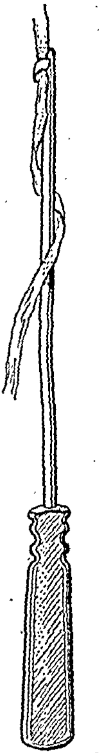


Tubular director.

We have modified Stokes's cutter, so that only one skin incision is necessary, and the introduction of the instrument into the fascia has been made almost automatic. Every member of the surgical staff of the Meath Hospital has had a hand in improving this tool, and we desire it to be known as the "Meath Hospital fascia cutter" (Fig. 1). It is, in the main, an open ring or horseshoe-shaped knife with the cutting edge on the distal end, blunt at the proximal end, fixed on the end of a 10½ in. steel stem with a good-sized handle giving a firm grip.

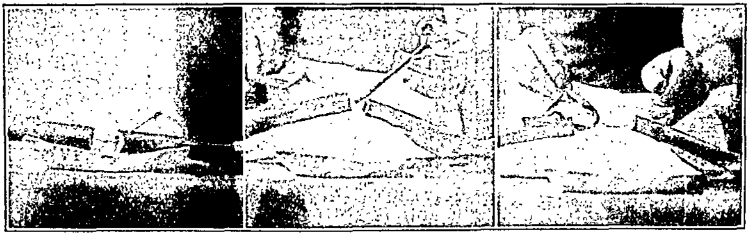
In use an incision 1 in. to 1½ in. in length is made on the outer side of the lower end of the thigh 2½ in. above the knee, and in an oblique direction from above downwards in order to expose the fascial fibres somewhat transversely. The fascia lata now laid bare is dissected free of fat, not merely at the bottom of the wound, but under its upper edge for an inch or more. It is then picked up with an Allis's forceps (Fig. 2) and the sharp free edge of the cutting hook of the knife is pushed through the base of the ridge so formed, making thereby two incisions (Fig. 3), the width of the strip of fascia between these incisions depending on the height of the ridge raised. The distal end of the strip thus made is seized with an artery forceps and *held taut*, while the hooked knife is pushed along subcutaneously in the line of the fibres of the fascia up the thigh as far as it will go (Figs. 3, 4, and 5). A rotatory movement of the instrument on the fascia strip, which is still held taut, will generally sever it from its upper connexion. Occasionally this manœuvre may fail owing to the strip falling out of the hook, in which case the knife should be withdrawn, the strip again threaded through the hook and given one twist around the shank of the instrument (Fig. 6). The knife is now advanced to the top of the strip again, the strip is held taut, and the knife is pushed obliquely upwards

FIG. 6.



Strip of fascia twisted round shank of fascia cutter.

so as to make an angle of about 20° to 30° with the strip. This brings the cutting edge of the knife across the fascial fibres and will always cut free the strip.



FIGS. 8–10.—Method of using a tubular director in suturing bone.

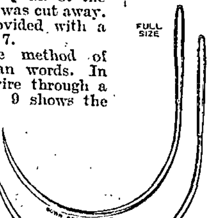
It is essential to obtain the strips of fascia from the outer side of the thigh, for here the cross fibres are practically absent and the fibres accordingly split far more easily than in front or elsewhere where the cross fibres are well developed. This also applies to Stokes's instrument. In practice we sometimes find it is better to cut several narrow strips of a convenient width for sewing rather than to cut one or two wide ones and have to split them up later. The advantage of this instrument over the former tubular type is that it is self-entering into the fascia, and that the strip can be cut at its far end subcutaneously, only one skin incision thus being necessary.

Suture of Bone and Fascia.

The next instrument is a tubular director for use in suturing bone with fascia or wire. It was made originally by adapting a curved saline needle, the point of which was ground off and then the lower ¼ in. of the concave part of the tube was cut away. In its present form provided with a handle it is shown in Fig. 7.

Figs. 8–10 show the method of employing it better than words. In Fig. 8 it is guiding a wire through a hole in the bone. Fig. 9 shows the first step in suturing a fractured bone with a strip of fascia (a bit of tape is actually doing duty for the fascia here). A loop of fine snare wire is guiding a strip of fascia through a hole in one fragment. In Fig. 10 the director is guiding the loop of snare wire through the hole in the other fragment. To facilitate the passage of the snare wire loop through the hole in the bone and in the director the ends of the loop are twisted together. This tool will be found very useful for suturing bones with fascia or wire.

FIG. 11.



Needles for suturing fascia.

We come, finally, to our fascia suturing needles. Two of these are shown in Fig. 11. We have replaced the eye of the ordinary triangular-edged muscle needle with a small flat loop of wire about 1 in. long. This needle is, of course, only an extension of Arthur's original plan of using a loop of silk. It may be threaded very easily with the aid of a fine-pointed artery forceps. The needle is not unduly heavy or wide, and is quite convenient in use.

The three instruments are obtainable from Messrs. Down Bros., of London. In their preparation we gratefully acknowledge the assistance given by the late Richard Lane Joynt, surgeon to the Meath Hospital, who made beautifully finished and improved instruments from the models we submitted to him.

Clinical and Laboratory Notes.

FŒTOR ORIS OF TONSILLAR ORIGIN AND CERTAIN BACILLI CAUSING IT.

BY ALDO CASTELLANI, HON. K.C.M.G., D.S.C.,
M.D. FLORENCE, F.R.C.P. LOND.,
DIRECTOR OF TROPICAL MEDICINE, ROSS INSTITUTE, LONDON;
LECTURER ON MYCOLOGY, LONDON SCHOOL OF
HYGIENE AND TROPICAL MEDICINE.

As is well known, fœtor oris (halitosis) may be due to a variety of causes. More often than is perhaps suspected it is due to some chronic pathological condition of the tonsils, such as, for instance, granulomycosis of the crypts. In certain cases of granulomycosis a most offensive odour is emitted when the granules are extracted and squashed. The granules contain many different germs: bacilli, cocci, nocardias, monilias, spirochætes, fusiform bacilli, and sometimes even amœbæ and flagellates. In two of my cases I have isolated and grown from these granules certain bacilli which produce in agar culture exactly the same offensive odour as was noticeable in the patient's breath, and on squashing the white granules. Moreover, I have isolated these organism in four cases of fœtor oris in which the tonsils appeared normal except for some enlargement, and in two cases in which they did not even seem to be enlarged. The individuals, however, had a very offensive breath, and in making swabs from the tonsils and fauces the same two germs were grown (Bacillus I. from three cases, and Bacillus II. from the others). Of course, many other organisms were also present but none of them produced any smell in cultures. The smell is most noticeable in agar cultures kept at 35° C. for 12–24 hours. After three or four days the cultures lose the odour unless the tubes are rubber-capped, when the odour may be noticeable even after five or six days. The odour is not present, or only very slightly, in glucose agar cultures.

Bacillus I. is a motile, Gram-negative bacillus, easily stained by the usual aniline dyes. It does not liquefy gelatin or serum, it clots milk, and produces acid and gas in lactose, glucose, lævulose, maltose, galactose, saccharose, mannitol, sorbitol, raffinose, arabinose, xylose, dextrin, and glycerin. The biochemical reactions are shown in the table.

Bacillus II. is a motile, Gram-negative bacillus, easily stained by the usual aniline dyes. It does not produce gas in any sugar, it does not clot milk, and does not liquefy gelatin or serum. The biochemical characters are shown in the table.

Biochemical Reactions of Two Bacilli.
(Incubation period, 7 days.)

—	Bacillus—		—	Bacillus—	
	I.	II.		I.	II.
Motility	+	+	Sorbitol	AG	0
Gram	0	0	Inositol	0	0
Gelatin	0	0	Rhamnose ..	AG	0
Serum	0	0	Adonitol	0	0
Litmus milk ..	AC	0 Alks	Raffinose	AG	0
Lactose	AG	0	Arabinose ..	AG	0
Glucose	AG	0	Xylose	AG	0
Lævulose ..	AG	0	Dextrin	AG	0
Maltose	AG	0	Amygdalin ..	0	0
Galactose ..	AG	0	Erythritol ..	0	0
Saccharose ..	AG	0	Inulin	0	0
Mannitol ..	AG	0	Glycerol	AG	0
Dulcitol	0	0	Indol	0 or S	0
Salicin	0	0			

0 = absence of clotting in milk, absence of acidity and gas in sugar media, absence of liquefaction in serum and gelatin. A = acid. G = presence of gas. S = slight reaction.

Conclusion.

Fœtor oris of tonsillar origin does not seem to be rare. In some cases evident lesions of the tonsils are present, such as white grains in the cryptæ. In other cases no gross lesions are present, the tonsils being merely enlarged and at times apparently normal. In this type of case, swabs from the tonsils and fauces will reveal the presence of bacteria producing, when grown on agar, the same smell as that noticeable in the patient's breath. According to the classification introduced by Chalmers and myself, Bacillus I. belongs to the genus Escherichia, Bacillus II. to the genus Alkaligenes. For Bacillus I. the name *Escherichia colofœtida* (*Bacillus colofœtidus*) might be used; to Bacillus II. the name *Alkaligenes alkalofœtidus* (*Bacillus alkalofœtidus*) might be given.

I shall be pleased to supply workers interested in the subject with cultures of the two bacilli.

A CASE OF HERMAPHRODITISM.

By John Glaister, M.D. Glasg., D.Sc.,
PROFESSOR OF FORENSIC MEDICINE, THE UNIVERSITY OF EGYPT, CAIRO.

THROUGH the courtesy of Prof. Roy Dobbin, the Royal School of Medicine, Cairo, I had an opportunity of examining this interesting case which had been admitted to the Gynæcological Section of Kasr-el-Aini Hospital.

The patient was diagnosed as suffering from a Bartholin cyst and was recommended for admission to hospital. "She" had doubts as to her exact age, which was given as 18 years, and her nationality was Egyptian. Her parents had died while she was an infant and there is no history of previous illness. Menstruation had never appeared and the patient was unmarried. About ten months before admission her attention was directed to a small lump about the size of an olive stone in each of the labia, and about two months later these had commenced to swell, but remained more or less painless. The bowel and bladder function was stated to be normal and micturition was painless. The general facial appearance suggested masculinity. The eyebrows were bushy, and some hair, although not of a very coarse character, was present on the upper lip, the chin, and the upper portions of each cheek. The forearms, upper arms, lower limbs, and thighs were muscular and hairy. The hands and feet were large, the shape of the fingers being distinctly masculine. There was some prominence of the scapulæ and the base of the sacrum and pelvic outlet were narrow. The pubic arch was not wide-angled. Hair was plentiful over the upper part of the back and the base of the neck. Examination of the chest revealed the absence of female breasts, the mammary regions being definitely masculine in appearance, and there was an entire absence of female areolæ. Throughout the examination, the patient was inclined to be emotional. The pubic hair had been removed according to Egyptian custom. The labia majora were well formed and on palpation of these structures a localised mass was detected in each; the mass on the left side was about the size of a plum-stone and its margins were more definitely demarcated than that on the right side, which was rather larger, less clearly defined at the margins, and not so tense on palpation. Manipulation did not elicit complaint of pain or discomfort. The swelling on the left side could be pushed up into the inguinal canal, whereas that on the right side was only reducible with difficulty to the interior of the ring but not to the interior of the canal. Circumcision having been performed at an early age—an Egyptian custom—only a stump indicated the root of the clitoris or penis. The vaginal opening was represented by a small area covered with mucous membrane into which the urethra opened. There was no vaginal orifice but only an invagination of the mucosa which did not admit even the tip of the little finger. Rectal examination failed to reveal the presence of any internal female genital organs. A history of sexual inclination was not available. It should be noted that the voice in this case was of female type.

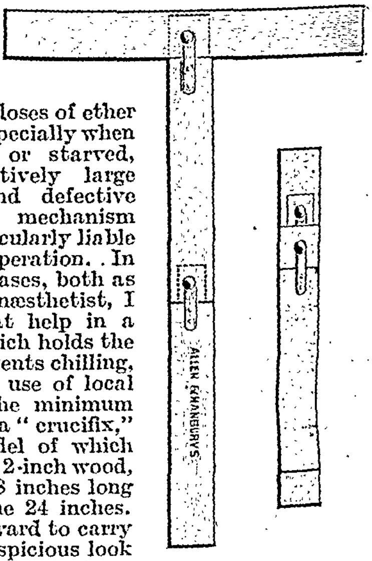
After observation in hospital it was decided not to undertake operation, and therefore a histological examination of the small labial masses was not possible to determine the absence or presence of gonads, although the absence of the majority of the secondary female characters, the male form of the body, the large bone formation, the well-developed muscles, and the growth of hair, in conjunction with andromastia, might reasonably suggest their presence.

This case is, I think, of considerable interest to the medico-legal expert, who from time to time may be called upon to express an opinion on doubtful sex cases.

New Inventions.

AN AID TO OPERATIONS ON INFANTS.

IN operating on babies there are certain special difficulties. Owing to their light weight and powers of contortion they need careful holding for greater or less time, according to the type of anæsthetic, and their small size makes it difficult for the holder to avoid the operators. They are very sensitive to overdoses of ether or chloroform, especially when they are toxic or starved, and their relatively large surface area and defective heat regulating mechanism make them particularly liable to chills during operation. In work on these cases, both as operator and anæsthetist, I have found great help in a simple device which holds the child firmly, prevents chilling, and permits the use of local anæsthesia or the minimum of general. It is a "crucifix," the original model of which was a simple T of 2-inch wood, the cross limb 18 inches long and the main one 24 inches. As this was awkward to carry and had an inauspicious look about it when taken into a private house, I devised a collapsible model in duralumin, with a sponge rubber padding, and this has been very satisfactory. The baby is wrapped in warm cotton-wool over as much of its body as possible according to the operation to be done, and is bandaged firmly to the frame. Subcutaneous salines or artificial respiration can be given without removing it. Incidentally, it is interesting to see how often a restless baby will settle down and go to sleep as soon as it is firmly fixed. It suggests that possibly there were advantages, at any rate to the parents, in the tight swaddlings which so many nations used for so many ages. The manufacturers are Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, London, W.1.



DENIS BROWNE, F.R.C.S. Eng.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PSYCHIATRY.

AT a meeting of this Section, held in conjunction with the British Psychological Society on March 11th, the chair was taken by Sir ROBERT ARMSTRONG-JONES, President of the Section of Psychiatry. A discussion on the

RÔLE OF PSYCHOTHERAPY IN THE PSYCHOSES

was opened by Mr. H. DEVINE. He said that his first hope that the new teaching might cure some of his psychotic patients had not been realised. The causal factors in mental illness were more complex and sinister than appeared at first sight, for the original notion of sexual trauma as the essential factor in neurosis had had to give place to that of "congenitally determined libido-fixation," a term sufficiently resembling "psychopathic heredity" to damp the hopes of ardent psychiatrists. So far as the psychoses were concerned the therapeutic possibilities of psycho-analysis were practically negligible; Freud himself had stated that the future would probably attribute far greater importance to psycho-analysis as the science of the unconscious than as a therapeutic procedure. The failure might be ascribed to various factors—e.g., the inability of the patient to coöperate, his imperfect sense of illness, the institutional relationship between patient and doctor, the lack of a suitable technique, or the definite physiological disorder related to the psychoses. Dr. Devine had at one time hoped that paranoia might be amenable to analytic therapy but had been disappointed. Karl Abraham, Pierce Clarke, and others had reported favourably on the analysis of manic-depressives between the attacks, but Dr. Devine had always found the depressive patient singularly impenetrable. The psychosis was the expression of an obscure disturbance of physiological rhythm, and when the attack was over the sooner the patient forgot all about his illness the better. Analysis in the interval might only give him more psychological material to express when he became ill again.

To say that at present we had no specific remedies capable of curing psychoses was not to say that treatment had no value. On the contrary, nowhere in medicine were therapeutic efforts more necessary and at times better rewarded, and among them psychotherapy undoubtedly held a very high place. A large proportion of the daily activities of doctors and nurses in a mental hospital must be included under the heading of psychological treatment. To refuse to admit that psychotherapy could influence the psychology of a patient because his body was biochemically unwell would imply that the mind was altogether independent of the body. Even the administration of a vaccine or a mere physical examination might have striking psychological results. Though the psychotherapeutic methods used in mental hospitals could not be called causal or specific they were not haphazard and unsystematised. At the outset it was essential to take seriously what the patient said, as a free outlet for his beliefs relieved tension and at the same time gave the psychiatrist essential knowledge of the phenomenal world of his patient. Clinical, physiological, and psychological studies all served to reveal different aspects of the same reality, although the morbid impressions of the psychotic could not be suggested or analysed away. As the psychiatrist could not dissipate what was abnormal his main task must be to develop what was normal, to stimulate social consciousness, and to help the patient to pass from purely individual impressions to broader social relationships which he could share with his fellow men. Mental therapy aimed at exercising the function of consciousness, in the hope that the narrow, morbid, psychic content might melt away or at least be relegated to the background as wider social relations became established. It relied upon simple, natural stimuli such as music, games, occupational therapy, and general conversations, treating the patient as if he were sane and helping him to regain the art of living, to attach his emotions and sentiments to external objects, and to exercise his intellect. This therapy, though unimpressive, was often successful. It was essentially active, and the psychiatrist could not remain in the background as a shadowy figure like the analyst; he had to be friend as well as doctor. It was difficult to disentangle mental from physical treatment, for the manner in which a patient was nursed was almost as important as the actual attentions themselves. In the psychoses, as in other illnesses, recovery was something that happened, independent in a great degree of therapeutic efforts. The old French saying "Je le pansay, Dieu le guerist" expressed a very real truth. Psychotherapy, however, was a method which did something to stimulate the biopsychic organism to regain its normal state of equilibrium in relation to its social environment. He did not question the valuable services rendered to psychiatry by the various schools of psychopathology, particularly the work of Jung on dementia præcox. The mechanisms described by Freud were constantly exhibited in psychotic patients, but it was his impression that psycho-analytic practice had not kept pace with the increasing elaboration of its theory. At the moment when something happened within a patient, so that he became uncertain of the reality of his delirious experiences, it was essential to utilise all the therapeutic arts, for injudicious handling at this crisis might drive him back into his dreams once more.

Psycho-analysis in the Psychoses.

Dr. E. A. GLOVER said that the analysis of maladapted personalities led to a qualitative familiarity with mechanisms which, given a quantitative factor, were commonly regarded as psychotic—e.g., the mechanism of projection—which in the normal individual performed the same protective function as in paranoid states. Psycho-analysis had been primarily constructed for the hysteria and obsessional neuroses, in which a relative stability of ego function existed, the ego giving asylum to the neurosis and trying to encapsulate it and continuing to exercise its important function of reality proving. The foundations of psychosis were laid when, to a profound instinctual disturbance was added a disturbance in the structure of the ego. Many of the sensational features of the manic-depressive group in the depressive phrase were due to a usurpation of ego function by the super-ego, while the exalted phases were characterised by an abandonment of function by the super-ego. Depressive states represented a malignant hypertrophy and exalted phases an acute descending paralysis of this unconscious conscience. The forces which stimulated the hypertrophy of the super-ego were essentially the destructive and particularly the sadistic impulses. At the moment when externally directed activity was slowly blanketed by inhibition, the internal regulative system was gradually heating up under the strain of additional sadistic charges until it finally flamed into the state of melancholia. Transference involved a temporary splitting of the ego into its components and the projection of the super-ego on to the analyst. The urgent aim in the treatment of melancholia was the speedy provision of the safety-valve of an externalised and undamageable unconscious conscience. If the super-ego were insufficiently projected, the depression could not be prevented, but the acuteness of the crisis could be lessened by modifying the super-ego by lending it some degree of tolerance, and by rescuing the ego by lending it some degree of resistance. This was done by gathering up the most urgent sadistic material, interpreting it, and indicating the possibility of a more tolerant super-ego and a more resistant ego—in other words, by lessening internal guilt. The manœuvre involved complete absence of impatience, a close scrutiny of every critical manifestation, and a feeling artificial pneumothorax was seldom recommended for the elderly patient, age need not necessarily be a bar if other conditions were favourable. Thoracoplasty was contra-indicated, and tuberculin rarely necessary, though in afebrile cases of slowly progressive type its cautious use might be permitted.

In conclusion, Dr. Young briefly referred to extra-pulmonary types of senile tuberculosis, lupus and surgical tuberculosis of the genito-urinary system being the least uncommon.

Discussion.

Dr. E. J. MACINTYRE spoke of the difficulty of controlling such cases and referred to the percentage of unnotified cases of patients over 50 years of age in the Borough of Bermondsey for the years 1925–29. In industrial areas especially it was important to have close coöperation between the general practitioners and the tuberculosis officers, and between tuberculosis officers and the officers of poor-law institutions.—Dr. V. S. HODSON said that the really important question in regard to prevention was the method of infection. Was it exogenous or endogenous? If endogenous, the tubercle bacilli had remained latent for many years, but there was no inherent improbability in this. If the bacilli could remain latent for 10 or 20 years, why not 50? If senile tuberculosis was a first infection, why was it localised as a rule and so seldom generalised?—Dr. S. VERE PEARSON said that even very old patients could be made quite comfortable in a sanatorium. He had done artificial pneumothorax in one or two patients over 60 who had got on well. He had also given sanocrysin to one such patient with considerable benefit. He was glad that stress was laid on the danger of old patients infecting others, and he gave some instances of this from his own knowledge.—Dr. W. C. FOWLER asked whether high blood pressure was associated with active disease in senile tuberculosis.—Dr. H. O. BLANFORD said that it was obviously possible so to modify sanatorium conditions as to render it suitable even for old persons. One great benefit of this treatment which was sometimes apt to be lost sight of was the comfort and help given by trained tuberculosis nurses.—Dr. J. WATT said he had been struck by the number of cases in which the patient had given no history of contact with tuberculosis but in which on close questioning it was found that the mother or father had suffered from chronic bronchitis. He confirmed what Dr. Blanford had said as to the value of sanatorium treatment for old persons; bronchitis seemed often to be secondary to the tuberculosis instead of the other way about, and in many cases the bronchitis cleared up as the winter advanced.—Dr. J. R. DOBSON gave details of three senile cases he had had in 12 days, including a man 73 years of age.—Dr. DINGLEY said that the admission of old patients to sanatoriums depended partly upon the season of the year, but even more upon the type of sanatorium.—Dr. G. T. HEBERT confirmed Dr. Young's remarks as to the necessity of examining the older members of a family in which the younger members in succession developed the disease. Physical signs might be no guide whatever, especially in bronchitic cases. He often advised against sanatorium treatment during the winter for old people.—Dr. F. R. WALTERS, speaking from his experience both as tuberculosis officer and as sanatorium superintendent, said his impression was that senile tuberculosis was not as often notified as it should be, and he stressed the importance of examining sputum in all cases of chronic bronchitis, not only in the old. Senile tuberculosis was no exception to the rule that, apart from acute or subacute cases, a search into the history would often show a previous breakdown in health which was probably though not obviously tuberculous.

The CHAIRMAN spoke of the difficulty of classification; tuberculosis in the young might be senile in type, and tuberculosis in the aged might be acute in type. Senile tuberculosis in the larynx might be very difficult to diagnose. At Midhurst he had only had three cases sent as tuberculous which turned out to be malignant, but on the other hand he had had literally dozens of cases sent to him as cases of malignant disease of the larynx which proved to be tubercle. In the majority of senile patients with tuberculosis of the larynx the sputum remained negative for years. He joined issue with Dr. Young about treatment, because if these patients could not be sent to sanatoriums, what was to be done with them? Patients who neglected themselves, in whatever social class they might be, died. He gave notes of several illustrative cases, including two in whom the disease was arrested but recurred, and both patients died. Old patients were much less likely to get over a relapse.

Reply.

Dr. YOUNG said he believed in practically all cases the infection was endogenous. Reactivation was often due to reinfection, or rather, superinfection. He did not wish to be thought in any way to criticise sanatoriums; it was simply that as they were usually run they were not suitable for the very old.

DIAGNOSIS AT A TUBERCULOSIS DISPENSARY.

Speaking on the problems of differential diagnosis, Dr. P. ELLMAN (tuberculosis officer, East Ham) said that at a tuberculosis dispensary there was a great temptation to consider cases sent up with symptoms of progressive loss of weight, fever, hæmoptysis, and so on, as potential cases of pulmonary tuberculosis. These symptoms, however, were not uncommon in other pulmonary and extra-pulmonary lesions. The speaker then referred to cases he had himself met with whose histories led him to suspect the possibility of pulmonary tuberculosis. Of these, the most commonly met with were cases of *naso-pharyngeal sepsis* with a secondary bronchitis, or even what was often termed "catarrhal apices," producing cough with blood-stained expectoration, general malaise, and loss of weight. Almost any nasal, pharyngeal, and sinus affection would produce a secondary bronchitis, localised or generalised, with symptoms resembling those of pulmonary tuberculosis. The next most frequently met with type of cases was *mitral stenosis*, and here a routine location of the apex-beat was of great value. In these cases the symptoms simulating pulmonary tuberculosis were, of course, due to pulmonary congestion secondary to the mitral disease. A third group consisted of cases of *specific aortitis* with or without aneurysmal dilatation and aortic regurgitation. X ray screening would clear up the diagnosis in these cases. *Neoplasms* of the lung in his own experience came fourth in in order of frequency, although doubtless in the experience of others this group would take an earlier place. Any patient of middle age with a series of chest symptoms which might suggest pulmonary tuberculosis but which were out of all proportion to the physical signs should be suspected of suffering from a neoplasm. He had had several cases of *bronchiectasis* with histories and in some cases physical signs almost identical with those of pulmonary tuberculosis. Here the value of an injection of lipiodol was well recognised; indeed, in certain cases where physical signs were limited to the apex or upper lobe it was almost impossible to distinguish between fibrosis, tuberculosis, carcinoma, and bronchiectasis without a lipiodol injection. *Hyperthyroidism* was another condition in which the symptoms closely resembled those of pulmonary tuberculosis, and the speaker described three cases of exophthalmic goitre suspected of phthisis whom he had recently seen at the dispensary. Dr. Ellman then referred briefly to the *pneumomycoses* and *pneumonokonioses*, and described an interesting case which proved to be one of broncho-moniliasis. Finally, the speaker suggested that a dispensary to work efficiently should be a department of a hospital where all facilities were available, or at any rate it should be in close contact and have a working arrangement with a hospital.

The **Chairman** spoke of the value of X rays in clearing up difficult diagnoses.—Sir P. H.-S. **Hartley** believed that pulmonary tuberculosis began at the apex and worked downwards. Hilum tuberculosis, except in very young children, was very rare. In tubercle he thought there was always some small alteration in percussion note, and he urged the necessity of a careful examination of the apices in regard to this point. Mitral stenosis and tubercle were once believed to be antagonistic, but although the combination did occur it was certainly very rare. He himself had never seen a case of exophthalmic goitre with pulmonary tuberculosis. He thought it was incumbent on the tuberculosis officer not only to state that a given case was not one of tuberculosis, but also to give a definite opinion as to the condition responsible for the symptoms.—Dr. F. A. **Lucas Hammond** said that as sanatorium superintendents they were often compelled to follow up mistakes that had already been made. It was sometimes difficult to alter diagnoses sent up to them by people who ought to know; and in other cases it might mean depriving a man of his pension. One condition not mentioned by Dr. Ellman was hepatic abscess; he himself had had two such cases sent to him, which cleared up under emetine. Many cases of fibrosis were really cases of silicosis, not recognised as such. He thought they ought to go through every case with a completely unbiased mind.—Dr. C. H. C. **Toussaint** concurred with the last speaker in regard to the number of patients sent to sanatoriums as tuberculous who were not tuberculous, and he showed a number of slides illustrating some of these cases.—Dr. P. A. **Galpin** (tuberculosis officer, West Ham) said that he had had a number of cases of neurosis sent to him as tuberculous. These cases were sometimes of considerable difficulty, showing symptoms such as loss of weight and of appetite, cough, expectoration, and sometimes signs at one apex. The neurosis developed as a result of the stress and strain of domestic life. Banti's disease, or splenic anæmia, sometimes masqueraded as abdominal tuberculosis. He had also had one or two cases in which underweight was the striking feature, but which he believed were really cases of infantilism. Cœliac disease might lead to difficulty in diagnosis; and this he thought sometimes led to infantilism. Cases of chronic pneumonia should, he thought, be kept under observation.—Dr. **Young** drew attention to the possibility of dysentery leading to a mistaken diagnosis of pulmonary tuberculosis, illustrating this by two cases in his own experience.

PATHOLOGICAL SOCIETY OF MANCHESTER.

At a meeting of this Society on March 12th a paper entitled

Recent Work on Streptococci

was read by Dr. A. W. **Downie**. Before the work of the Dicks, he said, the view was held by some observers that scarlet fever was a local streptococcal infection of the throat, and that the general symptoms were due to a diffusible toxin produced by these organisms. This view was not, however, generally accepted until more direct evidence was obtained by experiments on man. A notable advance in the state of our knowledge was made by the Dicks, who produced scarlet fever in human volunteers by swabbing their throats with pure cultures of hæmolytic streptococci. They further demonstrated the production of toxins by means of skin tests in susceptible individuals. Further work on the production of antitoxic sera in horses, and the effect of such sera in the treatment of scarlet fever, and the results of active immunisation by injections of toxin, afforded additional evidence of the view that scarlet fever is primarily a streptococcal infection. Whilst scarlet fever antitoxin had proved valuable when used during the acute stage of the disease, the reports of various observers seemed to indicate that it is much less efficacious in the treatment of septic complications. Moreover, the reports published by Kinloch, Smith, Taylor, and others, and the experimental work of Parish and Okell, suggested that antitoxin immunity does not prevent local streptococcal infection. It had been found that toxins apparently similar to those obtained from cultures of scarlatinal streptococci are produced by hæmolytic streptococci from other human infections such as erysipelas, puerperal fever, and cellulitis. Whilst some of the published work seemed to show that the toxins of erysipelas and puerperal fever differ immunologically from those of scarlet fever, the evidence appeared to be in favour of the view that they are identical and can be neutralised by scarlet fever antitoxin. The difference between the toxigenic properties of scarlatinal organisms and those from other sources seemed to be quantitative rather than qualitative. Recent studies on puerperal sepsis in relation to antitoxic immunity as indicated by the Dick test, however, did not suggest an exact correlation between such immunity and immunity to streptococcal infection during the puerperium. Further, the cases recorded recently by H. Burt-White[1] did suggest that the treatment of puerperal septicæmia by scarlatinal antitoxin yields highly satisfactory results. In streptococcal infections, other than scarlet fever, it could hardly be expected that the results of treatment with antitoxic sera would be as good as in that disease, because all virulent streptococci of the hæmolytic group had not been shown to produce toxin, and toxin of the skin-reaching type was not the only means by which streptococci exert their pathogenic effects. In immunity to hæmolytic streptococci two factors apparently had to be considered: (1) antitoxic immunity, and (2) antibacterial immunity.

Dr. Downie described experimental work bearing on the nature of immunity to hæmolytic streptococci. A discussion followed.

---

[1] The Lancet, Jan. 4th, p. 16.

Brighton Hospitals.—At the meeting of the governors of the Royal Sussex County Hospital, the Duchess of Norfolk, the retiring president, spoke of a recent anonymous gift of £3000 towards the hospital's radium fund, and remarked that if people wanted to give a donation for anything special they could not do better than give it to this fund. No fewer than 335 motor accident cases were attended to during the year, 92 being admitted as in-patients, at a total cost to the funds of about £1500; and Brigadier-General Brownlow remarked that of that sum only about a quarter was recovered, and that the real trouble was that people from anywhere in the country who were brought in occupied beds for which local people had been waiting for weeks, and sometimes months. Viscount Brentford was appointed the new president.—The Royal Alexandra Hospital for Sick Children claimed, in its report, to be equal to any other children's hospital in the country; and notwithstanding the many additions and alterations in recent years there was still a waiting list of 60 or more patients. Owing to the operation of the Rating and Valuation Act the rates were £308 instead of about £30, and the general account had been overdrawn to the extent of £1000.—Brighton, Hove, and Preston Dispensary, the Hove branch being the Hove Hospital, showed a deficit on the year's working of £510; and it was claimed at the annual meeting of the governors that Hove Hospital was the first in Sussex to possess radium of its own and to hire it out to medical men and hospitals in the county.—In regard to the Sussex Throat and Ear Hospital, an extension scheme has been in the making for many years; but with £3000 in hand, the belief was expressed that operations would begin before the next annual meeting.—The Sussex Maternity and Women's Hospital celebrates its centenary this year. Last year's work marked a deficit of £1353. Private wards brought in £1000, an increase of over £200 compared with 1928. The Duchess of Richmond and Gordon accepted the presidency.—Erected 98 years ago, the Sussex Eye Hospital is to be rebuilt. More than half of the £25,000 needed has been raised, and it is hoped to begin building operations towards the end of this present year.

delegation of rule-making power. He thinks the proposed legislation will unduly limit the poisons in Part I. of the list and unduly enlarge the poisons in Part II. He objects to the ease with which unqualified persons will obtain a local authority's licence to sell Part II. poisons; licences, he predicts, will be refused only to criminals or lunatics. Unlimited opportunities will thus exist for the purchase of arsenic and nicotine preparations, to say nothing of lysol and hydrochloric acid, both of which, he says, are responsible for a large number of fatalities. It will be possible, he assumes, to purchase more freely than ever enough arsenical weed-killer to exterminate a village, but it will still be impossible to obtain the smallest dose of heroin for a cough without a prescription. Mr. GAMBLE'S lively criticisms indicate the kind of attack to which the draft Bill will be exposed. The medical profession will have its own points to press. The Committee received a strong protest against the harassing and unnecessary provision in Section 3 of the Dangerous Drugs and Poisons (Amendment) Act of 1923, which requires "an order in writing signed by the purchaser" from a doctor purchasing poison. This, says the Report, will be a point for the rule-making authority to consider. It is to be hoped that the Home Office will consider it more favourably than in 1923.

◆

UROBILINURIA.

DURING the 60 years since the first detection of urobilin by Jaffé, an extensive literature has arisen both upon its chemical composition and origin and upon its clinical significance. The test for this substance and its precursor urobilinogen in the urine has been used more on the continent than in this country. A recent contribution to the literature of the subject is a small monograph by OLAF BANG,[1] of Oslo, who gives an admirable summary of present-day views upon this subject, with notes on some useful original work.

It is generally agreed by observers that the formation of urobilin depends upon both intestinal and upon liver functions, since it is essentially formed in the intestine from the bilirubin secreted in the bile; after reabsorption from the intestine the urobilin is mostly disposed of by the liver, a small portion only escaping in the fæces in the form of stercobilin. Incidentally, there is no certain evidence that urobilin can be formed under any circumstances by the general tissues of the body, and it is thus some index both of the amount of blood destruction which is occurring, and of the functional efficiency of the liver as a whole. An excretion of urobilin in excess of the normal is generally regarded as a general expression of liver damage, but there is no agreement as yet on the limits of the normal. Different tests suggest different answers to this problem. BANG uses a modification of Schlesinger's original reaction, whereby fluorescence is produced in urine containing urobilin when zinc salts are added to it; the modification is that of Marcussen and Hansen, and consists in dissolving 1 gramme of powdered zinc acetate in 10 c.cm. of 96 per cent. alcohol; 10 c.cm. of weakly acidified urine are added, and one to two drops of 5 per cent. tincture of iodine; the mixture is shaken and filtered, and the maximum fluorescence occurs after 20–30 minutes standing if urobilin is present. With varying dilutions of urine and careful standardisation of the illumination BANG has found that this reaction gives a fairly accurately quantitative estimation, provided a few simple precautions are observed. Working with this test he has confirmed the findings of other recent observers that a slight urobilinuria is a constant normal finding. There is, however, a simpler *clinical* test. A red colour is produced when Ehrlich's aldehyde reagent is added to a urobilinogen-containing urine, and when this method is used most observers agree that more than the faintest traces are probably always abnormal. The Schlesinger reaction is the more delicate, and according to BANG, the results in a large number of cases indicate that the boundary between normal and pathological urobilinuria is probably a variable one, and that there is constantly a normal slight excess excretion in the periods following the taking of food. The normal excretion is high in the new-born, possibly of maternal origin, falls later to a minimum, and then shows a small but perfectly definite increase with increasing age.

In healthy men a pathological urobilinuria, which BANG regards as evidence of at least a temporary liver insufficiency, can be produced in various ways. One way is the artificial production of an alkalosis by high bicarbonate medication (controlled by BANG by estimations of the blood alkaline reserve), and the taking of a carbohydrate-poor or carbohydrate-free diet; such pathological "dietetic" urobilinuria may be observed for example in patients undergoing treatment of peptic ulcer, in states of hunger, and in some depressive mental states. In diabetes mellitus the cause can be traced to lack of carbohydrates and to associated liver defect. The beneficial effect of sugar upon a damaged liver is, of course, well known, and in calling attention to the effect of carbohydrate shortage upon liver efficiency, BANG has emphasised a point of some importance. In the diabetics under his observation, a pathological urobilinuria was present in almost all those in whom the sugar metabolism was at all seriously upset, and was a constant feature in 23 patients who were all taking a diet very restricted in carbohydrates; in four untreated diabetics on full diet no pathological urobilinuria was found until a strict diabetic diet was ordered. These results have convinced BANG that undue restriction of sugar in diabetes may do further damage to a liver whose function may already be defective, and that a diet should be given containing sufficient carbohydrate to abolish any abnormal urobilinuria. It seems that the *utilisation* of some 60 g. of sugar per diem is the approximate figure below which pathological urobilinuria is likely to occur; a higher amount than this may possibly act as a protection to the liver against the toxins to which diabetic patients appear to be particularly vulnerable. BANG is thus in accord with those who are against the reduction of the carbohydrate diet to a minimum in diabetes, because of the paramount importance of maintaining the functional efficiency of the liver.

SHOULD MEDICINE BE A MENDICANT?

THE day when the voluntary hospitals offered little beyond food and shelter to the sick poor is long past; since they grew to be institutions where sick persons are treated—and even on occasion healed—much of the virtue has gone out of their position as objects of charity. Such at least is the opinion of Prof. E. W. HEY GROVES, who, in delivering on March 13th the Harveian lecture at the Harveian Society of London, spoke with considerable distaste of the proficiency in the art of begging to which the voluntary hospitals had attained of late years. Never had donations to hospitals been so lavish, and yet all the large voluntary hospitals were in debt, depending on "maudlin advertisement and the undignified clowning of students in the streets" to keep them open. He described the methods used as mendicancy, but by the end of his enumeration they had assumed the proportions of highway robbery. That students do not consider a hospital collection to derogate from their dignity, and that the public is placidly amenable to this financial bludgeoning he thinks beside the point. Certainly there is no escaping from the fact that the present system leads to duplication of expensive apparatus in all the large hospitals, and that the demands of scientific medicine for elaborate equipment increase yearly. This is responsible for the enormous expenditure; the requirements of a well-organised hospital have reached a complexity which it is beyond the powers of philanthropy to satisfy, and the testimony of failure lies in the long lists of those awaiting treatment. Even a patient with malignant disease may wait months for a bed, while a man with a comparatively trivial disability will be kept from his work for an indefinite period, costing the public unnecessary sums for his maintenance. Already hospitals have to be provided by the State for classes of ailment which cannot be accommodated by the voluntary hospitals, such as fevers, mental and venereal diseases.

---

[1] Klinische Urobilinstudien in Sonderheit an normalen und "lebergesunden" Personen. Die Wirkung kohlehydratknapper Kost auf die Urobilinausscheidung. Die Urobilinurie der Diabetiker. Acta med. Scand., 1929 (Supp. xxix.).

In the past, said Mr. HEY GROVES the poor-law hospitals had not pretended to compete with the voluntary hospitals, either in equipment or staff. Under the new Local Government Act the London County Council would no doubt bring the equipment of certain hospitals up to date, but that would not in itself be sufficient to bring them into line with the voluntary hospitals unless their staffs were correspondingly augmented. The treatment of a consultant on the staff of a general hospital at the present time amounted, he said, to exploitation; the hospital consultant was attending the working men and women of one of the richest countries in the world, many of whom were drawn from the middle classes and who paid for their maintenance in hospital. The expenses of a large number of patients were paid by insurance companies, and the only person who remained unpaid was the doctor. The chief argument urged against nationalisation of hospitals was that the doctors would require to be paid; the national insurance scheme produced a large surplus every year which might well be employed to defray the cost of hospital attendances, but this would mean that the doctors would receive fees. Is this a waste of money? The man who wished to become a consultant, said the lecturer, unless he had private means, must struggle during his best years to acquire a competence, so that by the time he was successfully established he had lost the taste for research. There is, of course, another aspect of voluntary medical service, and it would be idle to pretend it is quite as quixotic as it sounds, but it is certainly true that the average consultant spends a large part of his working time at a hospital, and there is no real reason why he should go unpaid for it.

Mr. HEY GROVES did not content himself with criticism of the position as it stands; he had a constructive policy to suggest.[1] By arranging for payment by all patients, except the destitute, according to their means, the cost of apparatus and maintenance could be covered, and fees could be paid to the physicians and surgeons attending the cases. The cost of new buildings and extension of accommodation should be met by a State subsidy, without State control. A central governing body should be formed to coördinate the work of the voluntary and municipal hospitals in order to prevent duplication of apparatus, and to organise the greatest mass efficiency with the least possible expenditure. The cottage hospitals, particularly, should be affiliated to some larger hospital, so that operations and treatment beyond their capacities would never have to be undertaken by general practitioners in outlying districts. All this could be accomplished by an extension of the insurance system, and a demand for reform should come first from the medical profession. But nothing, he concluded, could be done until the sentimental idea of the voluntary system had been abandoned—an idea so false that the very name was ironical.

◆

AN APPEAL TO THE WHOLE PROFESSION.

THE work of the Royal Medical Benevolent Fund is, or should be, the urgent concern of the whole medical profession. A certain number of practitioners in their old age, through broken health or ill-fortune, find themselves in desperate circumstances with no one to whom they can appeal for help. It is for their assistance that the Fund exists, and the descriptions published by the committee of some of the cases relieved give the measure of its value. In the annual report for 1929, which was mentioned on page 603 of our last issue, reference is made to the strong feeling of the committee that appeals should not be made to the general public. The altruism with which the medical profession is usually credited should be sufficient to make distress among its own members an impossibility. The Fund also extends help to widows of medical men, and daughters who in later years find themselves without means of support; on the death of a practitioner assistance in the education of his young children is sometimes granted, and efforts are made to secure work for them later. Unfortunately, though the income of the grant department for 1929 shows an increase of more than £600 over that of the previous year, the funds available are still too low to make complete relief possible, even in cases where it is most urgently needed. Annuities are given only to the most needy, when there is no possibility of their affairs mending; grants are voted for a period of one year, and paid quarterly. All cases are investigated carefully, to assure the committee of genuine distress, before a grant is made, and subscribers and non-subscribers are assisted equally. The highest annuity which can be given at present is £40 per annum, which is often quite inadequate. A subscription of one guinea a year from every practitioner would make it possible to give sufficient help to all cases. Another suggestion, which should meet with a ready response, is that in case of personal illness the practitioner should send a cheque to the Fund in recognition of the services he has received from a colleague. Subscriptions are urgently needed, and those who are already subscribers can do a service by persuading others to contribute; personal appeals are likely to meet with a better response than printed ones. Subscriptions may be sent to the Honorary Treasurer of the Fund at 11, Chandos-street, London, W. 1.

[1] See also THE LANCET, 1928, i., 251.

But, as we have pointed out,[1] even when the Wassermann test is carried out by identical methods, the results obtained in different laboratories may differ very considerably—in as many as 25 per cent. of the cases. E. Joltrain and O. Naegeli lay especial stress on the importance of making a thorough and careful examination of the patient and not relying solely on the pathological findings. With this we are in full agreement, although it must be admitted that sometimes clinical methods of investigation will fail to discover any objective sign of syphilis—in "latent inherited" syphilis, as well as in the acquired disease. If, besides a positive blood Wassermann reaction, a positive spinal fluid reaction is obtained, the diagnosis of syphilis is almost certain, and it is almost certainly also an active syphilis of the central nervous system which demands prolonged treatment. A. Marie calls a positive spinal fluid a "danger signal," which may be discovered quite early by systematic examination of the cerebro-spinal fluid, and which, if properly treated, may enable us to avert the very serious nervous system complications of the disease, to which the positive cerebro-spinal fluid shows the patient to be predisposed. This is of the utmost practical importance. Most of the replies expressed the view that a positive serological reaction—even in the absence of all clinical signs—calls for specific treatment, but that the actual method and details of treatment vary with the age of the patient. In the young, and especially in the pregnant woman (as H. Montlaur points out) a positive reaction should mean a prolonged and intensive course of treatment, aimed at making the reaction negative; whereas in elderly people—who, as S. Bergel says, have passed the age of syphilitic aortitis, general paralysis or tabes—treatment should be moderate and cautious. In considering the value of the serological tests in hereditary syphilis, Morhardt in his summary suggests that the Wassermann reaction of the blood is not of great value, but that more importance attaches to parental antecedents and to clinical signs in the patient. This brings into relief the great difference between the prevalent French view of the incidence of hereditary syphilis and that current in this and most other countries. In France a child born of syphilitic parents, if it suffers from epilepsy, debility, an unexplained anæmia, dystrophies, or almost any conceivable symptom, is commonly regarded as being the victim of hereditary syphilis, even though the serological reactions are persistently negative. The sequel is often a course of intensive treatment, and E. Joltrain utters a warning against such indiscriminate medication, since he has seen it do harm in children when applied without any valid reason. In this country nearly every syphilologist treats apparently healthy children in syphilitic families, who have no other sign or symptom of the disease than a positive Wassermann reaction, in an endeavour to make the blood reaction negative and to prevent trouble in the future. It must be admitted that the attempt to make the Wassermann negative in cases of hereditary syphilis is not always successful, but granting this, it is desirable to treat the patient by giving alternate full courses of arsenic, bismuth or mercury and iodides, without troubling too much about the blood test.

Lastly, there are the two conditions known as Wassermann-relapse and Wassermann-fastness. The former refers to a syphilitic in whom the reaction of the serum is rendered negative but subsequently becomes positive again. It is usually the result of inefficient treatment. Such patients if young and strong, require intensive and continuous treatment for two or three years with arsenic, bismuth, mercury and iodides; if they are elderly but apparently well, and the syphilis is of long standing, they should be treated with care, and preferably with intramuscular or subcutaneous injections of soluble salts of bismuth or mercury (L. Hudelo). Wassermann-fastness, on the other hand, implies that at no time during the course of the disease has the serum reaction been negative. Fortunately this condition is uncommon, and in spite of various explanations of its causation—such as the administration of the remedial agents (arsenic and bismuth or mercury) concurrently instead of alternately, or the giving too many or too strong injections whereby the reacting tissues are exhausted—its pathology is still undecided. No one is able to foretell at the outset of the treatment which patient will show the condition, and this reminds us once more that medicine is not and probably never will be an exact science, because it deals with bodies whose chemical and physical make-up differs. Treatment which is usually difficult, though occasionally a spontaneous reduction to a negative has been reported, is well summarised by Hudelo. In the case of old syphilitics, 50 to 60 years of age without clinical signs, and apparently in perfect health, it is unnecessary to persist in treatment; for these are essentially cases of benign syphilis, and there is no need to upset the equilibrium of the patients by exposing them to the real risks of an indefinite course so as to avoid the dangers, often exaggerated, of a Wassermann-fast condition (Ravaut). With younger patients the case is different and serum Wassermann-fastness is often a sign of involvement of the central nervous system (in hereditary as in acquired syphilis) leading eventually to tabes or general paralysis. These patients should be carefully watched and periodically examined—the blood being tested every three months and the spinal fluid once a year. Oral or rectal administration of drugs may be helpful in such cases if intensive injections have to be stopped (Schulmann and G. Levy); and the advice of Milian and others that attention must be paid to general hygiene and tonic conditions, including a stay at the seaside or in the country should not be overlooked. There is still much difference of opinion about the value of non-specific protein therapy, malaria-therapy, injections of sodium thiosulphate in Wassermann-fastness, though in general paralysis the efficacy of malarial treatment is now well established.

MEASLES IN MANCHESTER.

THE Registrar-General's return has recorded an average of 12 deaths a week from measles in Manchester during the past month. The epidemic reached its height in the week ending Feb. 8th, although the attack-rate in the city is not accurately known, since only the first case of measles occurring in a household is compulsorily notifiable by the doctor in attendance, and the others are reported as they come to the notice of the school medical officer and in other ways. During the past five years the measles mortality-rates per 1000 living in the city have been 0·17, 0·20, 0·21, 0·16, 0·08, the figures being only slightly higher than those for the country generally over the same period. The disease is now more prevalent and the mortality is higher in the central and more crowded districts of the city. A large proportion of the deaths occur in children under five years of age, as is indicated by the following figures. In 1925 there were 129 deaths, 123 of which were of children under five years of age; in 1926 there were 156 deaths, 151 of which were under five; in 1927 there were 164 deaths, 156 of which were under five; in 1928 there were 123 deaths, of which 121 were under five; and in 1929 there were 60 deaths, of which 58 were under five. Every known case of measles is visited by a health visitor, who advises the public health authority as to the arrangements for nursing. In any case where poverty prevents the provision of proper nourishment for the patient, free or cheap milk is provided by the corporation. Wards are set apart at the infectious hospital for the reception of cases of measles in which the home conditions are unsuitable. The number of beds so allocated varies; at the present time the number is 40. During epidemic times as many beds as can be spared are set apart for this purpose, as it is believed in Manchester that this provision is of the utmost value in the nursing and treatment of bad cases. The subject of measles is dealt with in popular lectures which are given from time to time by medical officers of the public health staff. During times of epidemic, also, the aid of the district nursing association is called in, and cases are referred to it for nursing, a grant for this service being made by the corporation.

---

THE STOCKHOLM PÆDIATRIC CONGRESS.

THE second International Pædiatric Congress will be held at Stockholm on August 18th–21st, as has already been announced in our columns. The Crown Prince and Crown Princess of Sweden are the patrons of the Congress, and a Swedish organisation committee has chosen the following subjects for discussion:—

(*a*) The biological effect of direct and indirect ultra-violet irradiation;

(*b*) The physiological and pathological significance of the thymolymphatic system;

(*c*) The psychology and pathopsychology of childhood; their significance as a branch of pædiatric research and teaching, and their application in medico-social work.

The names of the introducers of these subjects will be announced in the near future, as well as the names of those announced in advance by their respective national committees as intending to take part in the discussion. Free debate will follow the introductory addresses by the announced speakers. We have also received an intimation that notification of "free lectures" should be in the hands of the organising committee by April 1st. It is evidently expected that, apart from reports and discussions which have already been arranged for, members of the Congress may desire to initiate debates on particular subjects, when, if the committee approve, from 15 to 20 minutes will be allotted to such "free lectures."

All communications are to be addressed to Dr. I. Jundell, Second International Pædiatric Congress, Stockholm, Sweden, and application for tickets of adherence should preferably be accompanied by the fee, sent as a cheque or money order, and all names and addresses should be printed in block capitals. The fee is 20 Swedish crowns for adherents, and half that sum for accompanying members of their families—a Swedish crown is 1*s.* 1½*d.* For these special pleasure trips have been planned.

AMSTERDAM CONGRESS OF CYTOLOGY.

THE second International Congress of Cytology is to be held in Amsterdam on four consecutive days early in August, either at Amsterdam or Groningen, the precise details to be decided later. The first subject will be the cell and its properties, when A. Gurwitsch (Moscow) will deal with the problem of mitogenetic radiation, and A. Krontowski (Kiev) will speak on carbohydrate metabolism in tissue cultures and its changes under various conditions. The third subject will be the properties of the living cell, either when stained vitally or on micro-section. Possibly there may be time to take up radio-sensitiveness at the same session, and a film by R. Canti (London) will be shown. On one of the other days A. Timofejewsky (Tomsk) will speak on the properties of the blood and connective tissue in culture, while W. Bloom (Chicago), successor and pupil of Maximow, will take as his chief subject the formation of blood in tissue culture. W. von Möllendorff (Freiburg) will deal with the potency of fibrocytes in culture and tissues. For another session the subject of growth and its relations to differentiation and regeneration has been chosen, and among individual contributors are mentioned H. C. Fell (Cambridge) on bone-tissue in culture, A. Policard (Lyon) on cartilage in tissue culture, and L. Doljanski (Paris) on cultivation of liver-tissue and the maintenance of its properties in culture. The subject will be closed with a contribution by A. Fischer (Berlin) on regeneration in tissue culture. A proposal has been made from various quarters to devote the fourth day of the Congress to a discussion on the significance of tissue culture in relation to the culture of bacteria and viruses. The suggestions are as yet provisional and any who wish to take part are invited to communicate before April 1st with the general secretary of the International Preparatory Committee, Frau Prof. Rh. Erdmann, Berlin-Wilmersdorf, Nassauische-str. 17. It is understood that the Histological Institute of Prof. G. C. Heringa in Amsterdam will provide the scientific centre for experimental work.

PRELIMINARY TRAINING FOR NURSES.

THE latest gift of the Rockefeller Foundation to University College Hospital is a preliminary training school for nurses, which was opened by Prince George on Wednesday afternoon. Such a school has been in existence for many years, but it has been inadequately housed. With increase of the number of beds has come a need for more nurses, and the admirable aim of the authorities is to enlarge the theoretical background of practical instruction, and incidentally encourage a better type of entrant. The variety and increasing scope of a nurse's life make a broad professional outlook more and more desirable, and the Rockefeller Foundation is anxious to support institutions which are likely to turn out competent administrators, teachers, and supervisors who can spread the best traditions and methods. The new school is well equipped for the work it has to do. It is on six floors, with separate dining-room and practice kitchen, a laboratory department, and a demonstration room which is fitted like a ward, so that the students will not feel lost on going into the main hospital. Like the students, nurses in training will have access to the anatomy school. Two sister tutors and a staff nurse will have their quarters in the school, and there is room for 20 students, besides the domestic staff. The period of preliminary training is two months. During the second month the students will visit the hospital daily and engage in ward work, and at the end of their term they will be examined in the theory and practice of nursing. If successful, they will then be accepted as probationers. Provision is to be made for Rockefeller students from abroad, who, having been awarded a year's Fellowship, come to England for further experience.

THE SURGICAL TREATMENT OF DEAFNESS.

MIDDLE-EAR deafness, or "conduction-deafness," consists of three principal groups, those due to suppuration and its results, those due to chronic non-suppurative middle-ear catarrh, and otosclerosis. Much interest attaches to measures for the relief of deafness due to the last-named disease, for it frequently advances to a very severe degree, and may be accompanied by excessive tinnitus, and is uninfluenced by any form of treatment. In the last two decades of the last century there was a considerable degree of activity in this direction, and numerous intratympanic operations were designed for the relief of all forms of middle-ear deafness, but the distinction between the various forms were not so well understood then as now. The essential lesion of otosclerosis is the growth of new spongy bone in the capsule of the labyrinth, with consequent fixation of the stapes and often also with occlusion of the fenestra rotunda. It is not to be expected that excision of the drum-membrane, or the establishment of a communication between the antrum and the meatus, as suggested by Malherbe in 1899, would achieve any permanent good in such cases, and they have not, in fact, been found to be successful. Kessel in 1876, and Lucas in 1885, reported the result of removal of the malleus and incus; in cases of stapes ankylosis the ankylosis was in most instances the result of suppurative disease; in deafness due to otosclerosis the results were unsatisfactory. Extraction of the stapes has been tried operators and successes have been claimed, but there are many drawbacks; when the ankylosis is complete, it is often impossible to remove the foot-plate, the delicate crura being broken off instead, while, after successful removal, the foot-plate is replaced by a membrane of connective tissue which will itself become the seat of invasion by bony masses as before. As long ago as 1897 Passow made an opening in the labyrinthine wall below the oval window, and reported two cases. In one of these the hearing of whispered speech improved from close to the ear to ½ metre, and the tinnitus subsided; in the second case the tinnitus disappeared after operation, but returned. Gunnar Holmgren,[1] in 1923, reported four cases of otosclerosis operated upon with the use of a binocular microscope. After exposing the inner wall of the tympanum by a mastoid operation, or by detaching the posterior half of the drum, a mucoperiosteal flap was turned forward from the promontory, an artificial window made, and the flap replaced. One case was not improved, but in the remaining three cases the hearing improved at first, then deteriorated, but remained better than before, and better than in the unoperated ear which had previously been the better of the two. R. Bárány[2] has operated on several patients by opening the perilymphatic space of the external semicircular canal and implanting a plug of guttapercha into the fistula; one patient was worse six weeks after operation, one became completely deaf several years later, but the remainder were not made worse, so far as he had the opportunity of examining them.

On these not very encouraging data, Maurice Sourdille[3] has recently elaborated a similar operation, which he performs in two stages, working with a magnifying lens or a binocular microscope. At the first operation the mastoid is opened, the membrana tympani is separated from its attachment along the postero-superior half of its circumference, care being taken to preserve its connexion with the delicate membrane forming the bottom of the external auditory meatus; following the resection of the entire outer wall of the attic, the chain of ossicles is examined through the microscope, and the head of the malleus resected with or without removal of the incus. The tympanic membrane is replaced and the bottom of the meatus made into a flap which envelops the incus and is applied to the refreshed inner wall of the attic, thus shutting off the tympanum from the posterior part of the middle-ear cleft. The second operation is performed after an interval of several months: a flap is lifted forwards from the region of the bend of the external semicircular canal, and an opening is made into the perilymphatic space, care being taken not to damage the membranous canal, and the little flap is replaced. Mr. Sourdille has performed the first operation ten times on cases of chronic progressive deafness, and the second operation, of opening the semicircular canal, three times. In cases of deafness of medium intensity, he has found so much improvement after the first operation that he has been able to defer the second stage. This operation is practically an ossiculectomy, and it is not clear in what way it can improve the hearing in a case of otosclerosis. It appears that he does not restrict the operation to the extremely deaf, as do Holmgren and Bárány, but considers it suitable to all cases of otosclerosis where bone-conduction of the 128 v.d. fork is maintained or increased. He states that the technical results have been excellent in all but one case, in which further operation was required, and claims that in an almost deaf ear, provided that the bone conduction is maintained, the hearing can be improved to several metres for loud conversation. He makes one surprising statement, which is at variance with Holmgren's experience; it is that improvement in the hearing and in the tinnitus occur equally in the unoperated ear. This would seem to be the result of auto-suggestion, and shows how difficult it is to estimate the functional results of treatment of the deaf, for it is well known that these patients will show a temporary improvement after all kinds of treatment. Mr. Sourdille does not say how long his patients have been under observation, but it is probable that a minimum period of two years is necessary before it is possible to state that improvement is permanent.

On theoretical grounds it would seem that the surgical procedure which offers the best prospect in the treatment of otosclerosis is the establishment, if possible, of a permanent opening in the bony capsule of the labyrinth, covered with a very thin epithelial graft, to take the place of the occluded oval window; but as the condition of the round window cannot be determined beforehand, all such operations must necessarily be tentative. A patient should not be submitted to an operation of this kind unless he is so deaf as to be unable to follow his occupation, and yet he must not have any considerable impairment of the labyrinth. It follows that surgical treatment is suitable only for a small proportion of cases of middle-ear deafness. It is just possible, however, that a surgical technique may be devised which may improve the hearing of a certain proportion of patients suffering from deafness due to otosclerosis, as well as to fixation of the stapes from other causes.

[2] Ibid., vol. vi., p. 260.

[3] Bull. de l'Acad. de Méd., 1929, cii., 674.

WE have to announce the death of Sir John Fagan, at Portarlington, at the age of 86. He was consulting surgeon to the Belfast Royal Hospital and the Belfast Hospital for Sick Children.

IT has been decided to hold the Third International Congress of Radiology in Paris at the end of July, 1931. The President will be Dr. Antoine Béclère, the Vice-Presidents Dr. J. Belot and Prof. Cl. Regaud (Paris), Prof. J. Cluzet (Lyon), and Prof. Réchou (Bordeaux), and the Secretary-General Dr. Ledoux-Lebard, to whom inquiries should be addressed at 122, Rue La Boëtie, Paris (8^e).

THE impending retirement is announced of Dr. Alfred Eichholz, chief medical inspector to the Board of Education. Dr. Eichholz, who is a Fellow of Emmanuel College, Cambridge, has been an inspector of schools since 1898. His reports on the problems of the feeble-minded were among the first investigations of the kind, and led to his being asked to give evidence before the International Commission on Physical Deterioration in 1903, and the Royal Commission on the Feeble-minded in 1908. His knowledge of the special schools in this country may well be unrivalled.

DONATIONS AND BEQUESTS.—The late Dr. John Buchanan, of London, left £4000 for bursaries at Glasgow University, where he graduated, to be used for the foundation of two bursaries in medicine, to be called the John Buchanan Bursaries; and £4000 to the University of Liverpool to maintain a lectureship in Esperanto and to stimulate by prizes the study of the language among matriculated students at other universities.—Dame Mary Hope Walker Cargill, of Lowther-terrace, Glasgow, left over £17,000 for Scottish charities, including £5000 to the executors for charity, £3000 to Glasgow Royal Maternity Hospital, £2000 to the Royal Samaritan Hospital for Women, Glasgow, and £1000 to the Hospital for Sick Children, Glasgow.—Mr. Harold Arthur Lowther, of The Wellington Club, W., and of Bicester, Oxon., left £1000 to St. Dunstan's Hostel for Blinded Sailors and Soldiers and £500 each to the London Hospital, the Middlesex Hospital, Charing Cross Hospital, and St. George's Hospital.—Mr. John Richard Ward, of Cross-street, Manchester, who left £30,694, gave one-third of the ultimate residue of his estate to the Manchester Royal Infirmary for the endowment of beds in memory of his wife and his late daughter, Ethel Railton Ward.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

LXV.—THE SIGNIFICANCE AND VALUE OF EXAMINATIONS OF MILK.

PART I.*

AN examination or analysis of milk may be undertaken with two objects, the first to ascertain the chemical quality and the second to determine the bacterial purity. Although medical practitioners are concerned with the chemical quality of milk, especially in relation to its nutritive value, it is the bacterial purity in which they are vitally interested.

Chemical Quality.

Milk is such an important article of diet for young children and invalids that it is imperative that the richness of its important constituents should be maintained. On the other hand, milk is so easily sophisticated that a constant watch must be kept on the quality of what is sold. Local authorities under the Sale of Food and Drugs Act, 1928, which codified all the requirements of previous Food and Drugs Acts, are compelled to appoint public analysts and to take samples periodically for the analysis of milk along with other articles of food and drugs, and generally to administer the requirements of the Act. A medical officer of health, or a sanitary inspector, or a specially appointed officer may at any time take samples of milk and submit them to the public analyst for analysis. These officers will always act on a complaint from a medical man when deficiency in the quality of the milk is suspected. So active have the local authorities been during the last 20 years that the sophistication of milk has very greatly declined. The possibilities of avoiding detection are so remote and the penalties on conviction are so great that the game is not worth the candle.

The usual methods of sophistication of milk are by abstracting some of the milk-fat, by adding skim or separated milk and so reducing the percentage of fat in the whole, or by adding water, which reduces not only the fat but the proteids, sugar, and other constituents.

The general appearance of the milk is but a very rough guide to the quality, and is of little or no value. So also is the estimation of the cream, which rises by the action of gravity after the lapse of a certain time. Milk may be quite genuine, yet the cream may not be very evident in the cream-tube. Temperature affects the rising of the cream, but the treatment to which the milk may have been subjected at the dairy has a much greater influence. For instance, if milk is heated above 160° F., as happened with the old method of "Flash" pasteurisation, which will be discussed later, the amount of cream which rises, or the "cream-line," as it is termed in the milk trade, is adversely affected. Again, if the milk has been homogenised, the amount of cream rising after even 48 hours may be very little indeed. In the process of homogenisation the milk is forced at great pressure through a steel disc perforated with small holes on to an agate plate. The effect of the splashing of the minute particles of fat on to the agate plate with great force is to break up the fat globules to such a small size that they fail to rise in the milk on standing. Milk so treated might, therefore, be misjudged as to quality, yet it contains all the constituents of genuine milk, the only difference being that the fat globules are so small that they will not rise. In at least one part of the London area homogenised milk has come to be appreciated by housewives because it is impossible for any member of the household to abstract the precious cream from the day's stored supply.

The only true test of chemical quality, it can therefore be assumed, is the estimation by analysis of the main constituents. In an analyst's report the composition of the milk is stated as so much milk-fat, so much non-fatty solids, and so much water. In the non-fatty solids are included the sugar, proteids, and mineral salts. The average composition of genuine cow's milk is as follows:—

Fat			3·76
Non-fatty solids	Sugar	4·75	9·04
	Proteids	3·57	
	Mineral salts	0·72	
Water			87·20

By the Sale of Milk Regulations, 1901, made by the Minister of Agriculture, the composition of genuine milk is presumed to be not less than 8·7 per cent. milk solids and not less than 3 per cent. fat. It is very rare that milk from a herd of cows gives less than 8·7 per cent. milk solids, or less than 3 per cent. fat, so that when the former are reduced in percentage below that amount it is presumed that water has been added, and that when the fat is lower it is presumed that fat has been abstracted. Milk containing less than these percentages of constituents, especially if it comes from single cows or small herds in midsummer, may nevertheless be genuine.

Variations in Chemical Composition.

The chemical composition of milk varies with the breed of the cow, its individuality, the period of lactation, its age, the thoroughness with which milking is carried out, the quality of the feeding, the intervals between the milkings and the season of the year, but the variation is chiefly in the fat content, the variation in the non-fatty solids not being marked on any occasion. It is comomn knowledge that breeds such as the Jersey, Guernsey, Devon, Ayrshire, and others produce milk richer in fat than the Shorthorn, which is the most common dairy cow, and that individual cows give a higher percentage of fat than others. The most important of all these factors, however, is the length of the interval between successive milkings. The longer the interval between the milkings the lower the percentage of fat, and since the interval between the morning and afternoon milking is usually much shorter than that between the afternoon and morning, it follows that the milk produced at the afternoon milking has a much higher percentage of fat. In individual cows the difference may be as much as 50 per cent. By making the intervals as near as possible equal, the quality of the morning and afternoon milk may be kept about the same. This factor is therefore, to a very large extent, within the control of the farmer.

By a now famous legal decision, Hunt *v.* Richardson, if the farmer proves that the milk examined was as it came from the cow, no conviction can be recorded even though the purchaser is prejudiced by receiving milk of poor quality. A considerable amount of discussion arose on this legal decision and on other decisions which followed it. Some on the one side contended that the result would be that the farmer would not aim at improving the fat content of the milk produced by his stock, that adulteration would be more likely to escape being penalised by the simple expedient of bringing proof that the milk was as produced by the cow, and that the purchaser should have some guarantee of quality and should not be prejudiced. On the other hand, the farming interests contended that, even though many adulterations might escape from the deserved penalty, no farmer should ever be penalised for selling poor yet genuine milk, and that the remedy was to pay for milk according to its fat content, milk of a higher fat content being met with a higher price. In any case, the law stands as decided by Hunt *v.* Richardson.

Analysis will detect the presence of colouring matter and preservatives, such as boric acid, in milk but, as the addition of these is specifically forbidden by law, and as their value has come to be regarded as slight from the dairyman's point of view, it is rarely that suspicion of their presence arises.

---

* Part II. will appear next week.

Bacterial Purity.

The question of bacterial purity may be considered from two points of view, the first in regard to milk produced with special precautions, as in graded milk, and the second in regard to milk infected by bacteria which are likely to produce disease in the human subject. Ordinary market milk may contain any number of bacteria up to millions per cubic centimetre, the number of bacteria present having a distinct relationship to the care with which it has been produced at the cowshed, the manner in which it has been handled in its transit to the consumer, the temperature at which it has been maintained, and the time it has been kept. The total bacterial content is estimated by adding definite quantities of diluted milk to liquefied nutrient agar, which is then poured into flat Petri dishes and incubated at 37° C. for 48 hours. At the end of this time the colonies of bacterial growth, each originating from a single bacterium, are counted and the number of bacteria per cubic centimetre used for dilution is calculated. Coliform bacilli are presumed to be present if, on the addition of milk or dilutions of it, 1 c.cm., 1/10 c.cm., 1/100 c.cm., and so on, to bile-salt lactose broth, acid and gas are produced after incubation at 37° C. for 72 hours, the results being stated as coliform bacilli present in so much milk but absent in the next highest dilution in which a negative result is obtained. For example, the following is the bacteriologist's report on a sample of milk taken in September last year:—

Bacteriologist's Report.

No. of sample .. .. 3 .. Sept. 17th, 1929.
Temperature on arrival .. 22° C.
No. of bacteria per 1 c.cm. .. 113,000
  1/100 c.cm., 1107
  1/1,000 ,, 111
  1/10,000 ,, 12
Presence of *Bacillus coli*, 72 hours.
  1/100 c.cm. .. .. 1. Positive.
  1/1,000 ,, ... 2. Positive.
  1/10,000 ,, ... 3. Negative.

Graded Milk.

The Milk (Special Designations) Order has made it possible for the consumer to purchase milk of certain definite grades, produced under definite conditions, and with some guarantee as to bacterial content. These grades are not readily understood by the public, and their names do not convey any idea of their quality, so that the medical practitioner is often referred to for information regarding them and his advice is often sought as to their value, particularly in regard to their use by young children. An endeavour may, therefore, be made to point out as shortly and as clearly as possible the characteristics of the various grades, which are shown in Table I.

First of all comes *Certified milk*—the highest grade—which must be obtained from a tuberculin-tested herd of cows, which must be produced with the exercise of strict cleanliness and be cooled and bottled at the farm where it is produced. The cap of the bottle must have printed on it the name of the producer, the day of production, and the name of the grade. It should not contain more than 30,000 bacteria per c.cm., and the absence of coliform bacilli should be proved in 1/100 c.cm. With a healthy stock of cows, with all the cleanly precautions at the farm, and with the sealing of the bottle before it sets out on its journey, there is a guarantee of high quality and freedom from infection. Unfortunately, its cost is double that of ordinary market milk, and therefore can only be purchased by limited numbers of the community.

The next in quality is *Grade A (tuberculin tested) milk* which also must be obtained from a tuberculin-tested herd and produced with particular care and cooled at the farm. It need not be bottled at the farm, and is usually transported in labelled churns to the retailer's premises, where it is bottled. This grade of milk is allowed up to 200,000 bacteria per c.cm., and coliform bacilli must be absent in 1/100 c.cm. A high degree of security from disease-producing organisms is obtained in this grade of milk, many samples of which often show as small a number of organisms as Certified milk. It can usually be purchased at 50 per cent. above the price of ordinary market milk.

Grade A milk, which is often thought by members of the public to be the highest grade of milk, comes next in the scale of grades. It is produced with particular care at the cowshed, but the cows only undergo a physical test at regular intervals. The milk must be cooled at the farm, but need not be bottled there. It is allowed the same bacterial content as the previous grade. This grade does not give much guarantee of freedom from the bacillus of tuberculosis, and, in the view of many, does not deserve inclusion amongst the special grades on account of this. It is the standard which should be insisted on for all market milk at the present time, and the Government ought to take its courage in both hands and insist upon it. There is no need for elaborate buildings to produce milk of the quality of Grade A. What is wanted is the exercise of intelligent care and reasonable cleanliness on the part of the farmer and his workers.

Table showing the standards required under the terms of the Milk Special Designations Order, 1923, for the various designations which it is illegal to use in connexion with the sale of milk, except under licence granted by or under the authority of the Minister of Health.

(A) *Raw Milk.*

Designation.	Herds.	Bacterial content.	
		Maximum bacilli per c.cm.	Coliform bacillus.
1. Certified.	Tuberculin tested and physically examined at regular intervals.	30,000	Absent in 1/10th c.cm.
2. Grade A. Tuberculin tested	Ditto.	200,000	Absent in 1/100th c.cm.
3. Grade A.	Physically examined at regular intervals.		

Other conditions.—(1) *Certified Milk*: Bottled on the farm, name of farm, day of production, and word "Certified" on each bottle cap.

(2) *Grade A tuberculin tested, and* (3) *Grade A.*—Delivered to consumers in (*a*) the bottles or the sealed containers as received from the farm; (*b*) suitable containers of not less than two gallons capacity; (*c*) bottles with the name of dealer by whom the milk was bottled, the address of the licensed bottling establishment, the day of production and the words "Grade A Tuberculin Tested" or "Grade A" on each bottle cap.

(B) *Pasteurised Milk.*

Grade A Pasteurised.—Grade A milk that after pasteurisation as required by the Minister of Health, contains not more than 30,000 bacilli per cubic centimetre and no coliform bacillus in 1/10th c.cm. All other conditions as required for Grade A milk.

Pasteurised.—Any milk that after pasteurisation, as required by the Minister of Health, contains not more than 100,000 bacilli per cubic centimetre. No requirement for bottling.

These last two grades must be delivered to the consumers in the bottles or the sealed containers as received from the farm, in suitable containers of not less than two gallons capacity or in bottles with the name and address of the dealer by whom the milk was bottled, and with the day of production and the name of the grade on the cap of each bottle.

THOMAS ORR, M.D., D.Sc.,
Medical Officer of Health and School Medical Officer Ealing.

CROTCH v. MILES.

ACTION FOR ALLEGED NEGLIGENCE IN THE KING'S BENCH DIVISION.

IN the King's Bench Division, before the Lord Chief Justice and a special jury, an action for alleged negligence was brought against Mr. Ernest Miles by Mrs. Martha H. G. Crotch, the allegation being that a pair of forceps had been left in the plaintiff's abdomen, following an operation upon her performed on November 27th, 1920. It was admitted that an operation had been performed, but it was denied that the forceps had been left in the plaintiff's body. While it was pleaded that the action was barred by the Statute of Limitations, the defendant, through counsel, expressed the intention of giving evidence in answer to the charges.

CASE FOR THE PLAINTIFF.

Mr. J. W. Morris, in opening the case for the plaintiff, said that an operation was performed in 1920 upon Mrs. Crotch, who was then living at Richmond, for the removal of a fibroid tumour, and that after the operation her life had been one of continual ill-health and suffering. In 1922 and 1923 Mrs. Crotch travelled to India and back, and on both occasions she was taken ill, while previously, some five months after the operation, a swelling had appeared near the incision which the plaintiff had pointed out to the defendant, who had reassured her as to its cause. In 1925, when engaged in business in Paris, she became ill and was taken into a hospital, and the following year, when carrying on business in the south of France, she was again taken ill. On this occasion an operation was performed on her, after examination at a clinic in Nice, for the removal of gall-stones. Two years later the presence of the forceps in the abdomen was discovered by X rays, a return of pain having taken her to a doctor who advised the procedure. The forceps were removed in September, 1928, since when the patient had been relieved from pain. Mr. Morris submitted that the history of the case was inconsistent with the forceps having been left behind as the result of the operation for gall-stones, and that they must have been where they were discovered since 1920.

Mrs. Crotch said in evidence that after the operation in 1920 she had abdominal pain and a lump in the region of the incision, and returned to Mr. Miles, who accounted for the pain by the fact that the muscles had not recovered from the necessary injury which they had received, but that the symptoms would disappear. This, she said, did not occur, and no organ in her body seemed to function properly; for eight years she had suffered misery. She said that medical men in India and France had been unable to ascertain the cause of her attacks, and, in answer to the Lord Chief Justice, she stated that a metallic taste in her mouth, which she had complained of, was experienced in 1922, long before the forceps were discovered.

The Lord Chief Justice himself examined the forceps, and gave their measurements as about five inches in length and two and a half inches in breadth. The X ray photographs were at the disposal of his Lordship and the jury.

In cross-examination Mrs. Crotch accounted for the pecuniary claim in detail, including under the headings the cost of failure in a perfumery business, and the expenses incurred for the operation for gall-stones, inasmuch as the gall-bladder would not have been affected had not the forceps been left in her abdomen. No doctor, she said, had suggested an X ray examination until the summer of 1928.

DR. RICHARD HENRY EASINGTON STEVENS.

Examined by Mr. MORRIS.

Do you practice at No. 8, Sheffield-terrace?—I have now moved to No. 9, Campden Hill-road.

Are you a Member of the Royal College of Surgeons and a Licentiate of the Royal College of Physicians?—I am.

Did the lady who has just come from the witness-box ever consult you?—Yes, in 1921, 1922, and 1923.

Have you preserved a record of the dates on which you in fact saw her?—I have.

Perhaps you would just give my Lord and the members of the jury the dates?—I saw Mrs. Crotch in 1921 on Sept. 20th, Oct. 4th and 9th, Nov. 20th, 21st, 22nd, 24th, 25th, 26th, 27th, 28th, Dec. 8th and 28th. In 1922 I saw her in February on the 2nd, 3rd, and 28th, the 29th April, May 6th and 18th, and June 23rd, and in 1923 I saw her on August 29th.

I think you also attended upon Mrs. Crotch's brother?—Mrs. Crotch's brother, Mr. Gordon.

The dates which you have given to my Lord and the members of the jury are dates of attendances upon Mrs. Crotch?—Yes, Mrs. Crotch and not her brother or her husband.

You are quite certain about that?—Perfectly.

Perhaps you would tell my Lord and the members of the jury what Mrs. Crotch complained of when she saw you?—She was complaining of a pain low down in the abdomen, a swelling in the middle line of the abdomen, irregularity of the bowels, and attacks of nausea and vomiting.

Did you know that an operation had been performed upon her in the previous year?—Yes.

Did you in fact examine Mrs. Crotch?—I did.

Was there or was there not a swelling on her abdomen?—There was an abdominal hernia, a ventral hernia as it is called.

THE LORD CHIEF JUSTICE. When did you examine her?—1921 I think, my Lord.

Are you not sure?—I am not sure of that, but I am certain that I must have examined her. I cannot remember the exact date.

And what you saw was a ventral hernia?—A bulging.

What is the meaning of the word "ventral" there?—I believe you would call it the belly.

A bulging of the belly?—Yes.

Mr. MORRIS. I think that, other than the records of dates of which you have told my Lord and the members of the jury, you have not any actual notes written at the time about the case?—No, I am sorry, I destroyed them last year.

As regards your fees, have you been paid by Mrs. Crotch for attendance?—Not by Mr. Crotch but by Mrs. Crotch.

How much?—It was ten guineas in all for Mrs. Crotch.

And you have been paid that?—Yes.

If a pair of forceps were lying inside the small intestine might that cause inflammation of the gall-bladder or some infection of the gall-bladder?—An infection of the gall-bladder can be secondary to an infection of the bowel, and usually is.

Cross-examined by Mr. RAYNER GODDARD.

Did you diagnose this hernia at the beginning of your attendance on this lady?—Yes, the first time I examined her, the date of which I forget, there was a bulging which was obviously a ventral hernia.

THE LORD CHIEF JUSTICE. You are asked, did you diagnose a ventral hernia? If you are using the word "hernia" as being just another name for bulging that was a thing which was obvious on view, was it not?—Yes, my Lord, but by "hernia" I mean a bulging of the contents of the abdomen and not of the wall of the abdomen, a bulging of the contents through the wall.

That is to say, that it involves a burst somewhere?—Yes, my Lord.

Mr. Rayner Goddard. Is not a ventral hernia, as it is called, a fairly common sequel to an abdominal operation in a fat subject ?—Very common indeed.

It is formed, is it not, by a stretching of the scar ?—Usually, yes.

Is it a matter in which surgical help is sought ?—In most cases surgical advice is sought, and a belt is prescribed, if no radical operation is advised.

You did not advise the lady to go back to Mr. Miles ?—I cannot remember.

So far as you know she did not go to any surgeon ?—So far as I know she did not.

You were continuing attendance on her on many occasions during November, and two occasions in December of 1921. What were they for ?—For attacks of pain and sickness.

Was that the same during 1922 and 1923 ?—Yes.

I will give you the condition which the French surgeon described of the gall-bladder when he operated. Dr. Prat described the gall-bladder as very diseased, very thickened, and adherent to the surrounding parts. He says he performed the operation at an acute stage when there was fever, swelling, and pain. Would that description be consistent with the gall-bladder trouble being of long standing ?—Yes, but the attacks of pain which I saw in Mrs. Crotch's case were in the lower abdomen and not in the gall-bladder region.

The Lord Chief Justice. Would you mind putting your hand on the sort of places you are referring to ?—*That* is the gall-bladder, and *this* is the lower abdomen where most of the attacks of pain were when I attended her. The gall-bladder is just under the liver.

Where is the liver ?—Chiefly on the right side under the ribs and partly hidden by the ribs.

Mr. Rayner Goddard. Of course gall-bladder pain is very intense, is it not ?—Very intense.

And a patient whose gall-bladder was in that condition must have suffered from pain for a very considerable time ?—Probably, yes.

An affected gall-bladder, you say, may be secondary to an infection of the bowel ?—Yes.

The Lord Chief Justice. He said in fact it usually is.

Mr. Rayner Goddard. Do you mean by that that the cause of gall-bladder trouble is infection of the bowel ?—Most authorities say that it is an infection which travels up the bile-duct from the bowel.

It is still a matter as to which there is a good deal of doubt as to what causes gall-stones ?—Yes.

It is one of the things which medical science has not solved yet ?—No, but it is known it follows typhoid frequently.

That is just what I was going to put to you. If a person has typhoid, which is a serious bowel infection, that may affect the gall-bladder ?—Yes.

But except for infections of that sort that is as far as medical science has gone on the subject ?—I think so.

You do not know of any case in which an infected gall-bladder is supposed to have followed from a foreign body being found in the bowel ?—No, I have known it follow an appendix.

That is where you had definite infection, a sepsis from the appendix ?—Yes.

The Lord Chief Justice. I suppose cases in which a surgeon's forceps are left in the intestines are not counted in their thousands ?—No, I think not.

Mr. Rayner Goddard. And, of course, a surgical forceps which has been used in an operation would have been sterilised ?—Yes.

And had it not been perfectly sterilised a sepsis would have set up in the bowel ?—No, because the sepsis would have been set up in the abdominal cavity outside the bowel.

Do you know that it is said here that the doctor who removed the forceps thinks that it was in the intestine itself ?—I do not see how it could have got there.

Could it not have got there ?—Unless it had perforated its way through.

By perforation it could get in ?—Yes.

As you are here may I ask you about a modern operation. A modern operation is team-work, is it not ?—Yes.

The team consists of the surgeon, the assistant, the anæsthetist, and the theatre sister ?—And a couple of staff nurses and probationers.

I am not talking about general hospitals but a nursing home. There would be some assistants to carry basins and that sort of thing ?—Yes, there would be some nurses.

The Lord Chief Justice. A minimum of five persons and the maximum may be much more ?—Yes, my Lord.

Mr. Rayner Goddard. And, of course, during the course of an abdominal operation a considerable number of instruments are used and a large number of swabs, towels, sponges, and so forth ?—Yes.

Is it recognised in the profession now that the duty of keeping count of the instruments and swabs that are used in an operation is on the sister in charge ?—That is almost universally recognised.

The Lord Chief Justice. The theatre sister ?—Yes, my Lord.

Mr. Rayner Goddard. The surgeon's attention must be concentrated on the patient ?—Yes.

And I suppose in all operations it is desirable to get the patient off the table as quickly as possible ?—Yes.

Is it the anæsthetist's duty to give warning to the surgeon if the patient is showing signs of collapse ?—It is.

Is the moment when you want to ascertain whether the instruments, swabs, and sponges have all been accounted for the moment before the surgeon would begin to stitch up the patient ?—It is.

Would it be in accordance with the recognised surgical practice for the surgeon to cease the operation for the purpose of counting the instruments or sponges ?—No, that is unusual.

Assuming that a fully trained theatre sister is present, would it be in the interests of the patient that the surgeon should suspend the operation to do so ?—No, I should say not.

Does the surgeon then, when it comes to the moment when he is ready to sew up, ask the theatre sister if the count of instruments is right ?—Sometimes. Sometimes she volunteers the statement.

Either he asks or the nursing sister says "Count right" ?—That is the usual practice.

The Lord Chief Justice. She says "Count right," does she ?—She says "Instruments and swabs all correct."

Re-examined by Mr. Morris.

I suppose a surgeon sometimes does an operation with a trained nurse that he knows and sometimes operates with a trained nurse whom he may never have met before ?—Frequently so.

Would it make a difference to the surgeon as to whether he was operating with a trained nurse whom he knew and could rely upon ?—I do not quite understand the question—a difference in what way, a difference to his peace of mind ?

Would he place more reliance upon a trained nurse who knew him and whom he knew ?—Yes, probably.

About how long in time does an operation for total hysterotomy take ?

The Lord Chief Justice. Are you going to leave the question like that, Mr. Morris ? Is it not right to ask at least one other question. (To the Witness): Suppose that the nurse in the particular case is not known beforehand to the surgeon, is it or is it not in accordance with good practice that he should still rely upon her for an accurate count of the instruments and the swabs ?—If he knows her to be a trained theatre sister, my Lord, he would be justified in putting that confidence in her.

Mr. Morris. How long does an operation for total hysterotomy take as a rule ?—As a fair average I should say three-quarters of an hour.

The Lord Chief Justice. What does hysterotomy mean ?—It means excision of the uterus.

Then, to put it simply, to cut out the uterus takes about three-quarters of an hour?—Yes, my Lord.

MR. MORRIS. At the start of an operation like that would the forceps be laid out somewhere?—Yes, on the instrument table.

Would they be laid out in groups?—The Spencer-Wells, that is to say, the artery forceps, would be in a row. The other forceps would be in groups. There would probably be a dozen artery forceps, Spencer-Wells.

THE LORD CHIEF JUSTICE. Then you mean a dozen pairs of scissors?—Yes.

Not the single blade?—Not the single blade, my Lord.

MR. MORRIS. Before actually sewing up the wound would a surgeon feel round the wound, feel inside the body with his fingers?—He might, but the less manipulation the better in most of these cases.

As far as possible would he look inside?—Yes, he would.

THE LORD CHIEF JUSTICE. What is the objection to unnecessary manipulation?—Only that it increases shock to the patient.

MR. MORRIS. For what purpose are forceps of the nature of the forceps in the present case used?—I do not know what the forceps were in the present case.

THE LORD CHIEF JUSTICE. Would you like to look at them?

THE WITNESS. I would like to very much, my Lord. (Forceps handed to the Witness).

MR. MORRIS. What sort of forceps are those?—These are Spencer-Wells. They are used for clipping bleeding points and so stopping the bleeding.

You say they are used for clipping bleeding points. Does that mean that the two ends pinch the particular part where the blood is emerging?—Exactly.

What has the surgeon to do to see that that bleeding does not continue when he takes the forceps off?—He may either twist the forceps and so twist the end of the bleeding vessel or he may slide a ligature over the end of the forceps, tie it, and then remove the forceps, leaving the ligature tied on to the vessel.

So as to stop internal bleeding?—Exactly.

An expression has been put to you by my learned friend "team-work." Of that team, as it was put to you, in that operating theatre who is the captain?—The operating surgeon.

THE LORD CHIEF JUSTICE. Does not the word "team" perhaps rather beg the question? Is it so much a team as a division of labour, not all jointly doing the same thing but each separately doing a bit—I do not know.

MR. MORRIS. May I just get this from you. If the surgeon, after the door of the operating theatre has been closed, gives an order, must that order be obeyed?—Yes, the surgeon is in command then.

He tells somebody to do this, and must it be done?—Yes, except that the anæsthetist under certain circumstances has a say.

THE LORD CHIEF JUSTICE. But is it part of the surgeon's duty not merely to do the actual surgical work as it should be done but also to keep an eye on each of the others to see that each one does his or her part as it should be done?—It is, my Lord, as long as it does not distract too much of his attention from the patient.

The supervision is limited by his primary duty to look after the patient?—It is, my Lord.

MR. MORRIS. You were asked about one or two particular parts of the body. Would you be good enough to indicate where on the body this swelling was that Mrs. Crotch had?—As far as you can see on me just *there* (indicating) in the region of the navel.

THE LORD CHIEF JUSTICE. Just below the navel?—Yes.

MR. MORRIS. Is that what is also called the umbilicus?—Yes.

THE LORD CHIEF JUSTICE. Sub-umbilical means below the navel?—Yes.

MR. MORRIS. Is the operation for hysterotomy one that is sub-umbilical?—It is.

Is the operation for the removal of the gall-bladder supra-umbilical?—It is.

THE LORD CHIEF JUSTICE. That means above it, I suppose?—Above and to the right, as a matter of fact, my Lord.

Mrs. C. Young gave evidence that she had been the plaintiff's maid at the time of the first operation; she said that a month after her return home her mistress had shown her the abdominal wound, when she had seen a swelling.

DEPOSITIONS.

Depositions of witnesses examined in the action Crotch v. Miles, at Nice, in the Republic of France, before Mr. Joseph Wiseman Keogh, His Britannic Majesty's Consul, the Special Examiner appointed by an Order in this action dated 23rd December, 1929.

On the twentieth day of January, 1930, the examination commenced at mid-day. I, the said Joseph Wiseman Keogh, having first administered the oath as prescribed by the rules of the Supreme Court of Judicature, England, to myself, to Miss Renee Bonneau as clerk and shorthand writer, to Dr. Alfred Marie Vadon as interpreter, Mr. John W. Morris (instructed by Messrs. Churchill & Clapham), appeared for the Plaintiff, Mr. Henry C. Dickens (instructed by Messrs. Hempsons) appeared for the Defendant. It was agreed between Counsel for the Plaintiff and for the Defendant that the evidence should be taken direct on to a typewriting machine and that the signing by the witnesses should be dispensed with. I then administered the usual oath of a witness to, and caused to be examined, the following witnesses, who were produced before me on behalf of the Plaintiff to give evidence in this suit.

DR. HENRY FAY residing at No. 20, rue de la Buffa, Nice, having been first duly sworn by me, was examined by MR. MORRIS on behalf of the Plaintiff.

Are you Dr. Henry Fay?—Yes, I am.

Do you reside at 20, rue de la Buffa, Nice?—Yes, I do.

Are you a surgeon?—Yes, I am a surgeon.

Will you please tell us your qualifications?—I studied at the Faculty of Paris, and I qualified as M.D. in 1912.

Have you been practising as a surgeon since 1912?—Yes.

Are you the assistant at Nice Hospital?—Yes, I am.

Did you perform an operation on Mrs. Crotch on the 27th of September, 1928?—Yes, that is the date in my report.

(It was then agreed between Counsel that the original report referred to, dated the 27th of September, 1928, should be put in as the witness's evidence in part.)

Is that the report that you made?—Yes, I made that report myself.

(Report put in and marked Exhibit "A.")

You speak in your report of an X ray photograph. Had you seen an X ray photograph of Mrs. Crotch?—Yes, I saw it the day before the operation.

Had you seen one X ray photograph or two?—I saw two photographs.

Will you look at these two photographs, are those the photographs which you saw?—Surely.

(Photographs put in and marked "B" and "C" respectively.)

What was your fee for the operation?—I think about five thousand francs. But it has not yet all been paid.

Do you know how long Mrs. Crotch was in the clinic after the operation?—I think about one month.

Do you know Dr. Prat?—Yes, I do.

Is he a surgeon of eminence?—Yes, he is.

Was the laparotomic scar at the place where an incision would be made in an operation for total hysterectomy?—Yes.

Were the forceps at a place underneath that old scar?—Not completely, the end of the forceps was a little lower down than the end of the scar.

If forceps were being inserted in an operation would they be inserted by the surgeon himself ?—Sometimes the surgeon, sometimes the assistant.

If a pair of forceps was left inside the body after an operation for hysterectomy, would a swelling be likely to be caused ?—Yes.

Would it be likely to cause great pain ?—Yes.

Will you look at that pair of forceps produced. Are those the forceps which you removed from Mrs. Crotch ?—Yes.

(Original forceps made an Exhibit and marked " D ".)

Cross-examined by MR. DICKENS *on behalf of the Defendant.*

Did you tell Mrs. Crotch that your fee was five thousand francs ?—Yes.

How much of that have you been paid ?—I am not quite sure, but I think she owes me half.

Have you tried to get her to pay you ?—I wrote to her last October, I think.

Have you written more than once ?—I think I wrote three times.

Do you know whether the clinic has been paid ?—I think so.

Any operation inside the intraperitoneal cavity is difficult and dangerous ?—Always.

And it requires great care on the part of the surgeon ?—Yes.

And all his attention ?—Yes.

Such an operation is a hysterectomy ?—Yes.

And a cholecystectomy ?—Yes.

For operations of that kind the surgeon must be assisted by a team, an assistant and an anæsthetist and one or two sisters ?—Yes.

And each member of that team has his or her particular part in the operation ?—Yes.

And if the surgeon knows and trusts the members of the team he will not interfere with their particular part in the operation ?—Yes. He will not interfere.

For instance, he will not interfere with the giving of the anæsthetic ?—Quite so.

Is it not the practice of surgeons in such an operation to leave the counting and checking of the instruments and the swabs to a sister ?—It ought to be like that.

It is impossible for the surgeon himself to keep count of the instruments and swabs which he has put, or his assistant has put, into the body ?—He cannot know.

Then it is possible for a surgeon to leave instruments or swabs in the body without personal negligence ? (Mr. Morris objected to this question.)—Yes, it is possible.

What are the symptoms of cholecystitis ?—Pain in the sub-hepatic region.

What else ?—Fever, nausea ; sometimes pain in the back and in the right shoulder.

Cholecystitis is inflammation of the gall-bladder, is it not ?—Yes, it is.

That itself could not cause trouble in the bladder or in the lower part of the abdomen ?—No.

Or pain on defæcation ?—No.

Before you operated, did you make an external examination of the patient ?—Yes.

And did you, like Dr. Maestracci, discover something hard in the abdomen on palpation ?—Yes.

It was quite obvious, was it not ?—Yes.

And you could not have missed it ?—No.

On Exhibit " E " I have marked with a cross the ileo-cæcal valve and with a circle the duodenum. (Exhibit " E," " Vinton's Anatomical Model," was put in.)

When I said that the forceps occupied a point in the small intestine which one may locate almost half way from the duodenum and the ileo-cæcal valve I meant in the middle part of the length of the intestine (small).

Will you mark on Exhibit " E " exactly where the forceps were located ?—I have done so.

Will you look at Exhibit " C." Was that taken from the front or the back ?—I think from the front.

Does that photograph show the forceps in the position in which you have marked it on Exhibit " E " ?—Approximately the point of the forceps, as shown on Exhibit " C," is in the same position as I have marked it in Exhibit " E."

Are you quite sure of that ?—Yes.

Is not the dark part in the centre of Exhibit " C " part of the intestine ?—Yes. The large intestine.

And the point at the bottom of that dark part is the rectum ?—It is the end of the rectum, the sphincter.

The intestines are shown dark on Exhibit " C " as the result of a bismuth or barium meal ?—Yes.

If you diagnosed a swelling or any abnormality in the intestines you would try to find out what it was by giving a meal of bismuth or barium, and take an X ray photograph ?—Yes.

Any swelling of the intestine which was abnormal would show itself on an X ray photograph taken after such a meal ?—All dilatation is seen under such circumstances as a rule.

Any abnormality ?—Some sorts of abnormality could not be seen.

If you suspected some such abnormality as a swelling you would try this method ?—Yes.

Were the forceps found inside the intestine itself ?—I cannot say exactly whether it was in the tube itself or in a pouch formed by the intestines which were glued together by adhesion, but I concluded that it had been in the tube itself because there was fæcal matter on it.

These forceps have a screw in them ?—Yes.

Screw forceps are used in France, are they not ?—Generally no.

But sometimes yes ?—It may be, I have never seen them.

Do you know the name of F. Gendron ?—Yes.

Is he a well-known maker of surgical instruments ?—No.

During the war were there not English military hospitals on this coast ?—I was not here, I do not know.

Do you know that after the war the English military authorities sold a great quantity of surgical instruments in France ?—I did not know it.

Re-examined by MR. MORRIS.

Does hysterectomy mean the removal of the uterus and of the ovaries ?—Yes.

Is that what is known as total hysterectomy ?—Yes.

I think you have told Mr. Dickens that a surgeon ought to exercise great care in such an operation ?—Great care, yes.

Is it a very serious matter for a surgeon to leave a pair of forceps in the abdomen ?—Yes.

Does a surgeon count the number of his instruments after an operation ?—No, never.

When a surgeon uses forceps in an operation does he clamp the forceps on to some part of the body ?—Yes.

Is the reason as a rule to prevent bleeding ?—Either that or to keep some part of the body out of the way.

Has the surgeon to be skilful as to what part he clamps the forceps to ?—Yes.

And before the surgeon sews up the wound is it his duty to remove the forceps which are inside ?—Always.

DR FREDERICK AYLMER HORT, residing at No. 6, rue du Congres, Nice, having been first duly sworn by me, was examined by MR. MORRIS on behalf of the Plaintiff.

Is your full name Dr. Frederick Aylmer Hort ?—Yes.

Do you reside at 6, rue du Congres, Nice ?—Yes.

Are you a Doctor in Medicine and have you practised as a medical man for the last twenty-seven years ?—Yes.

Perhaps you will give us your qualifications ?—I am L.S.A., M.R.C.S.England, L.R.C.P.London, M.D.Montpellier, France, and a Fellow of The Royal Society of Medicine, London, and M.A. Cambridge.

Did you see Mrs. Crotch in the year 1926 ?—Yes.

Did you recommend Dr. Prat to Mrs. Crotch in that year?—Yes.

Is Dr. Prat a surgeon of experience?—A surgeon of great experience.

Did Dr. Prat operate on Mrs. Crotch?—He did, on the 8th of June, 1926.

Were you present at the operation?—I was.

For what did Dr. Prat operate?—For an infected gall-bladder.

Is your technical term for that cholecystitis?—Yes.

Does the gall-bladder lie just underneath the liver?—It does.

Did Dr. Prat make his incision in a place that would be usual for cholecystitis?—Yes.

Did Dr. Prat remove the gall-bladder in its entirety?—The bulk, if not all, of the gall-bladder was removed.

Was that operation in the sub-hepatic region?—That operation was confined to the region under the liver. The surgeon had to dig under the liver to get at it.

Did Dr. Prat deal in any way with the lower intestine in that operation?—No, not at all; he did not even explore the rest of the abdomen.

Have you been paid your fees by Mrs. Crotch?—I think she has paid everything she owed me.

Can you tell us what your fees were?—I do not remember exactly, but I think between frs. 1000 and frs. 2000.

Does a surgeon have assistants at an operation?—Yes, he has an anæsthetist, a doctor as assistant, and sometimes a sister.

Of those people who is it that would insert a pair of forceps in a patient's body?—Only the surgeon or his qualified assistant.

Who would remove the forceps before the patient's body was sewn up?—Only the surgeon or his qualified assistant.

Is it the duty of the surgeon to see that the forceps are removed? (Mr. Dickens objected to the question.)—The surgeon's, or his qualified assistant's.

Cross-examined by Mr. DICKENS *on behalf of the Defendant.*

You say you attended Mrs. Crotch for some years. Can you give me approximately the date when you first attended her?—I first attended her in the winter of 1925–26.

Did you attend her more or less continuously up to the date of her operation?—Yes.

I take it that you gradually diagnosed gall-bladder trouble?—My diagnosis would probably have been acute abdominal trouble—a more general diagnosis than of gall-bladder trouble.

By the time you called in Dr. Prat had you diagnosed gall-bladder trouble?—To all intents and purposes, yes.

The recognised symptoms of gall-bladder trouble are pain in the region of the gall-bladder?—Yes, acute pain.

Possibly pain in the back?—Yes.

In the right shoulder?—Yes.

Nausea?—Yes.

Anything else?—No.

I take it that as the lady's medical attendant, and as she complained of abdominal pains you had examined her very carefully more than once?—No doubt.

You were not surprised when Dr. Prat diagnosed an infected gall-bladder?—Not in the least.

He operated for cholecystitis and nothing else?—That is rather a difficult question to answer directly, for an operation on an acute abdominal condition is always more or less of an exploratory nature. In fact his operation was confined entirely to the sub-hepatic region.

You, yourself, after careful examination, had diagnosed no trouble except in that region?—None whatever.

Were you the assistant in the operation?—I was not the principal assistant, I think there was another.

Was there a theatre sister there?—Yes.

I take it, after this distance of time, you find it difficult to remember the details?—Certain details are difficult to remember.

I take it Dr. Prat would have had to use swabs?—No doubt.

Forceps to cut off the bleeding points?—Yes.

Those would be pressure forceps?—Yes, but we generally call them artery forceps.

A number would be used?—No doubt.

Do you know what system was adopted to count and check the swabs and instruments which were used?—No.

It is usual, is it not, to leave this counting and checking to the theatre sister if she is properly qualified?—I believe so in England.

Nowhere else?—Certainly not in France.

You do not suggest, do you, that the surgeon, whose whole attention must be concentrated on the actual operation, can keep count of the swabs and instruments which he or his assistant inserts into the body?—I think so in the case of Dr. Prat, because any deep swabbing he would do himself.

As to instruments, do you suggest that he would be able to tell you after the operation had gone on some time how many he or his assistant had used?—That is not my suggestion.

What is your suggestion about that?—My suggestion is that he would at any stage know whether or not any instrument was left in the body.

Do you mean because he could see them?—No, because they form part and parcel of the bit of work he is doing.

But supposing a pair of forceps which was attached to a bleeding point had slipped accidentally into the wound and become hidden either by blood or by the folds of the intestine, he could not necessarily be expected to know that that instrument was in the body, unless he had kept an accurate account of the instruments used?—It is conceivable, certainly, but it is very unlikely in that particular area, and under those particular conditions.

If the patient is in a state of collapse a surgeon would be more likely to fail to discover the presence of such an instrument?—I cannot say.

At this operation in the region of the gall-bladder the whole of the intestine would be below the region of the operation?—At an operation of this sort the intestines are liable to bulge in any direction.

And I suppose they are all covered with blood and mess, aren't they?—No, they are all shut off.

By swabs and towels?—Yes.

They are purposely shut off, firstly to keep them out of the way of the operation, and secondly to protect them from shock or injury or infection?—Yes.

But even so, under such circumstances, in any abdominal operation it is possible for instruments to become temporarily hidden in the intestines?—No, not in any abdominal operation, but in an operation such as this I suppose it is possible.

Dr. Fay is a surgeon of some repute in these parts?—Yes, he is a young surgeon and has not been here very long, but he is very well thought of.

You, yourself, are not a surgeon?—No.

Dr. Fay, who is a French surgeon, has told us to-day that no surgeon ever counts or checks the instruments used at an operation. Would you contradict that?—I am not in a position to say either way.

You continued then to attend Mrs. Crotch after the operation?—Yes.

Off and on?—Yes. Continuously through her convalescence and at intervals since.

Up till when?—Up to the present day.

Did she make a good convalescence?—To the best of my remembrance an excellent one.

Did Dr. Prat suggest to you that there was likely to be any further trouble after the operation?—No.

What sort of treatment did you give her?—Only dietetic treatment.

Did she complain to you from time to time of abdominal pain?—Never.

She saw Dr. Maestracci on the 12th of September, 1928, how long before had you seen her ?—I had not seen her for a considerable time probably.

Did she ever complain to you of urinary trouble ?—Not until after she had seen Dr. Maestracci.

Was it a normal operation of its kind ?—Perfectly normal with no complications.

Re-examined by MR. MORRIS.

You told Mr. Dickens that an operation for an acute abdominal condition is always more or less exploratory ?—Yes.

Will you explain a little more fully why it was exploratory ?—Because no one can be certain of what is going on inside an acute abdomen until he has looked to see.

The diagnosis is really provisional ?—I look upon the diagnosis of an acute abdomen as always provisional.

But in fact there was no exploration other than in the sub-hepatic region ?—None whatever, and for a very good reason, that the patient was not a good subject for operation ; she was fat, not a good colour, and it was to her interest to get her off the operating table as soon as possible.

You told Mr. Dickens that forceps are attached to a bleeding point ?—Yes that is what they are for.

Does the surgeon have to exercise his skill to decide exactly where to attach the forceps ?—Certainly.

When he removes the forceps has he to make some arrangements to see that the bleeding does not recommence ?—That depends on the bleeding. If the vessel is tied it is tied before the forceps are removed.

Is it the surgeon who does that tying ?—The surgeon or his qualified assistant.

Is the matter of bleeding one that the surgeon would have to consider before finally sewing up the wound ?—Yes, certainly.

DR. LOUIS PRAT, residing at No. 24, Avenue des Fleurs, Nice, having been first duly sworn by me, was examined by Mr. MORRIS on behalf of the Plaintiff.

Are you Dr. Louis Prat ?—Yes.

Do you reside at 24, Avenue des Fleurs, Nice ?—Yes.

Are you a surgeon ?—Yes.

For how long have you practised as a surgeon ?—Twenty-eight years.

Will you please tell us your qualifications ?—I am a Doctor in Medicine of the Faculty of Paris, ex-house surgeon of Paris Hospitals, surgeon to the Nice Hospitals, surgeon to the English Hospital of Nice, member of the International Association of Surgeons.

Are you a member of the French Association of Surgeons ?—Yes.

Are you also Chevalier of the Legion of Honour ?—Yes.

About how many operations do you perform in a week ?—About 25 a week.

Did you operate on Mrs. Crotch on the 8th of June, 1926 ?—Yes.

Did that operation take place at the Belvedere Clinic, at Nice ?—Yes.

Where did you operate on Mrs. Crotch ?—I operated in the hepatic region between the liver and the transverse colon adherent to the wall of the abdomen.

What did you do in the course of that operation ?—I removed the gall-bladder, which was very diseased, very thickened, and adherent to the surrounding parts. I performed the operation at a very acute stage when there was fever, swelling, and pain.

Did you explore any part of the abdomen other than the sub-hepatic region ?—I dealt only with the local condition as it would have been a mistake to do anything else as it might have given a peritonitis.

Had Mrs. Crotch had a previous laparotomy ?—Yes. I noticed a laparotomy scar and at the level of the scar I noticed either a sort of rupture with a swelling or a hard mass. I cannot remember exactly.

What did you consider that that was ?—I thought it was an epiploic.

I want you to explain further what you thought it was and what epiploic means ?—When I examined the abdomen of the patient I noticed that she had a laparotomy scar with an eventration, at the level of which I felt a swelling which I diagnosed to be epiploic. Epiploic means abnormal adhesions of the inflamed omentum.

Was the operation a difficult one to perform ?—Yes.

Will you look at Exhibits "B" and "C," two X ray photographs ? Is the part of the abdomen where forceps are shown in them anywhere near the region where you operated ?—No.

What pattern of forceps do you use ?—Kocher forceps made by Collin. They have no screw in them.

Instead of a screw what do they have ?—The two blades are detachable, and the type I use are quite different to the screw type.

Will you look at Exhibit "D." Do you use forceps of that pattern ?—No.

Do you ever use forceps of that type ?—Maybe during the war, and not for operation.

Do you use that type at the Belvedere Clinic ?—No.

Are those forceps of the Collin type ?—No.

Did you use those forceps (Exhibit "D") when you operated on Mrs. Crotch ?—No.

From the appearance of those forceps can you tell whether or not they have been in somebody's body for some time ?—I do not know, I have no experience of this kind of thing.

Did you see Mrs. Crotch after the operation in 1926 ?—I saw her afterwards, about three months ago.

Do you remember what your fees were for the operation ?—Mrs. Crotch sent me the last balance a few days ago ; I am not quite certain as to the amount. I think about four thousand francs.

Cross-examined by MR. DICKENS *on behalf of the Defendant.*

You had very great difficulty in getting your fees paid by Mrs. Crotch ?—Yes. It required a debt-collecting agent to intervene, and then I only got it in instalments.

French surgeons do sometimes use forceps with a screw ?—Probably.

I understand you yourself have seen such forceps ?—Yes, and I have seen one pair here to-day.

During the war there were British Military Hospitals on this coast ?—I do not know, I was in Belgium.

Do you know that at the end of the war the British Military Authorities sold large quantities of surgical instruments in France ?—No.

When you operate who hands you the forceps you want to use ?—I take them off the table myself.

Who is present at the operation ?—My house surgeon, the doctor, and the anæsthetist, and there is also a sister.

Sometimes does your assistant put in forceps ?—Exceptionally.

And the swabs ?—In principle the assistant puts in the swabs.

At your operations, who counts the swabs as they go in ?—Nobody counts them.

Who counts the forceps ?—Nobody counts them.

This operation was a difficult and dangerous operation ?—It was not a simple operation, fairly difficult, and it was dangerous on account of the general condition of the patient, who was also alcoholic.

She was alcoholic ?—I think so. A little. Her doctor told me so. She was not a teetotaller.

When a patient is in the condition in which this patient was, it is important to bring the operation to an end as quickly as possible ?—Yes.

Do you agree with Dr. Hort that during this operation the intestines were bulging in every direction ?—I did not see the small intestine. The transverse colon was swollen, and I had to push it down the whole time to take it out of the way. The colon was always inclined to get into the way of the operation.

It is possible, is it not, in such an operation for a pair of forceps, if it has become accidentally detached, to get among the intestines and to get hidden there?—No, I do not see that that could happen.

Why?—I left a drain in the wound and that would not have healed up if I had left a pair of forceps in the wound.

But if the forceps could have slipped down into the abdomen between the intestine and the wall it would not have affected the drainage of the wound, would it?—If it had slipped right down out of that region it might not, but it would if it had remained in that region.

Will you please mark on Exhibit "B" the line of your incision?—(*The Witness does so with a dotted line.*)

Now about this hard mass. Your recollection of this operation is naturally not a very good one?—My recollection is not very precise. When I examined the patient for a moment I thought of reopening the old laparotomy scar in order to re-make it, because I thought it was not in order; but I contented myself in doing the simple operation on account of the bad state of the patient.

Did you warn Dr. Hort about this?—I do not think so.

Did you tell the patient about it?—I do not think I did.

You were the only person who knew about this; why did you not warn either Dr. Hort or the patient about it?—I do not remember exactly what was at the level of the scar, I remember that the patient had abdominal trouble which had nothing to do with the hepatic trouble. Mainly there was defæcation trouble, a strong pain which we call tenesmus.

This trouble was abnormal and would have to be watched by the patient's doctor?—It had to be found out what was the trouble with this abnormal condition.

How would you find out what the trouble was?—How could I find out?

Could you not find out possibly by X ray with bismuth or barium what the abdominal trouble was?—Yes, sometimes the X ray would show the cause of the adhesions.

Did you not consider it your duty to tell Dr. Hort about this, so that he could have such an X ray photograph taken?—The patient left the clinic before her wound was completely healed, and I never saw her again, until recently.

But you saw Dr. Hort after the operation?—Probably. I have constantly seen him again.

But you never told Dr. Hort about it?—I never spoke to Dr. Hort about this case again.

May I take it that the first time that you mentioned this hard mass to anyone was in December, 1928?—I have never spoken of this case since the operation.

But you did mention it in December, 1928?—I forgot all about the case until I was asked by the Plaintiff's Solicitor to make a report. I then made a report, which I now produce, marked "F."

Re-examined by MR. MORRIS.

In the report which you have just mentioned (Exhibit "F") you say you noticed the existence of a swelling. Is that a reference to the hard mass of which you have been speaking?—Yes.

> It is agreed that the two photographs, "B" and "C," are to be admitted in evidence without calling the photographer.

The Examination was then adjourned until Tuesday the 21st inst.

Dr. DOMINIQUE MAESTRACCI, of No. 12, Avenue Henri Isnard, at Vence, having been first duly sworn by me, was examined by MR. MORRIS on behalf of the Plaintiff.

Are you Dr. Dominique Maestracci?—Yes.

Do you live at No. 12, Avenue Henri Isnard, Vence?—Yes.

Are you a Doctor of Medicine?—Yes.

Will you please tell us your qualifications?—I am an ex-house surgeon of the Paris Hospitals and Laureat of the Faculty of Paris. I am M.D. of Paris.

Did you examine Mrs. Crotch in September, 1928?—I examined Mrs. Crotch on the 12th September, 1928.

Have you made two reports about Mrs. Crotch?—Yes, I made one by myself and one in conjunction with Dr. Fay.

> (It was then agreed between Counsel that the original reports referred to and dated respectively 15th of October, 1928, and 27th of September, 1928, should be put in as part of the witness's evidence.)

Is that your report dated the 15th of October, 1928?—Yes, it is.

(Report put in and marked "G.")

Will you look at Exhibit "A"—is that the report that you signed with Dr. Fay, dated the 27th of September, 1928?—Yes.

Were you present when an operation was performed on Mrs. Crotch on the 27th of September, 1928?—Yes.

Did you administer the anæsthetic at this operation?—Yes.

Are the matters you speak of in your report all correct?—Yes.

Did you see Dr. Fay extract a pair of forceps?—Yes.

Will you look at Exhibit "D." Are those the forceps which Dr. Fay extracted?—Yes.

Are those forceps of a French make?—No.

When those forceps were in the body, how were they placed?—They were placed in the small pelvis.

In your report you speak of a frenulum, which passed through one of the rings of the forceps? Will you explain what sort of a thing that was?—It was what was left of one of the round ligaments which was formerly attached to the uterus. This is also called the broad ligament.

How did it come about that that frenulum was passed right through one of the rings of the forceps?—The round ligament had been cut at the first operation. The forceps were hanging by the ring through which the ligament had penetrated, and had formed adhesions to the intestine. The ring of the forceps was lying at the site of the adhesions resulting from the first operation.

Does that mean that the ligament of which you have spoken had grown?—No. The free end of the round ligament passed through the loop of the forceps and became adherent to the small intestine by the process of cicatrisation.

Would that process take some time?—Yes.

Will you look at the two X ray photographs marked "B" and "C" respectively. Where do those photographs show the point of the forceps to be?—Inside the small pelvis, on the right hand side.

Whereabouts were the forceps with reference to the external laparotomic scar on Mrs. Crotch?—On the right half of the scar, underneath.

Was the external laparotomic scar on Mrs. Crotch at the point where an incision would be made for hysterectomy?—Yes.

Whereabouts were the points of the forceps when they were found?—Inside the small pelvis on the right hand side.

For what purpose would you expect such a pair of forceps to be inserted?—For hæmostatic purposes.

Ought such a pair of forceps to be removed before the patient is sewn up?—Surely.

Do you remember what your charges to Mrs. Crotch were approximately?—Four thousand five hundred francs.

Have you been paid that?—Not at all. I have received nothing.

That is still owing to you?—Yes.

Did Mrs. Crotch's operation take place at the Clinique Ste. Marguerite?—Yes.

Before that operation had Mrs. Crotch undergone any treatment?—Yes, she told me she had had high frequency treatment.

But that treatment did not continue after she saw you?—No.

Do you know Dr. Prat?—Yes.

Have you seen him operate?—Yes.

Have you seen him operate a few times or often?—Often.

What kind of forceps does he use in his operations?—Collin type.

Have you ever seen him use any other type?—No.

Cross-examined by Mr. DICKENS *on behalf of the Defendant.*

You cannot say of your own knowledge that Dr. Prat never used forceps with a screw?—No, but I can only speak from what I have seen. In France surgeons are in the habit of using only detachable forceps, because there are no other kinds in the hospital services.

Will you look at this catalogue. On page 110 there is a pair of forceps with a screw?—It is not a hæmostatic forceps. Those are cheap forceps.

But they could be used in an abdominal operation?—Yes, but not by a conscientious surgeon.

Why?—Because they do not hold tight enough.

That is not because they have a screw?—No, because they are poor make and because they cannot be properly sterilised.

I suppose you have tried to recover your fee from Mrs. Crotch?—Yes.

Several times?—Yes.

Do you know whether the clinic has been paid?—I do not know exactly.

You have said that the process of cicatrisation to which you have referred must take some time?—Yes.

But of course you have no experience of how long it will take?—It certainly took a very long time.

But you have no previous experience of such a case as this?—I have had experience of foreign bodies in the abdomen, but never a forceps.

But adhesions can form in a few months?—Not identical with those of Mrs. Crotch.

When you examined Mrs. Crotch on the 12th of September, 1928, you had no difficulty on palpation in diagnosing something hard in the abdomen, and the presence of an obstacle in the passage of matter?—I had to palpate for half an hour.

You say in your report that on the left one can easily locate the intestinal loops, whilst it is impossible to do this on the right side. That pointed to something abnormal?—Yes.

And as a result of your examination did you advise her to have an X ray photograph taken as soon as possible?—I insisted on it.

It would have been a breach of your duty if you had not insisted on it, would it not?—Yes.

Dr. Fay said this in his evidence.—Dr. Fay made his diagnosis after I had told him of mine. It was I who brought the patient to him and told him my diagnosis, and so it was easy for him.

You had diagnosed something hard in the abdomen?—Yes, I diagnosed a foreign body in the abdomen. I told Mrs. Crotch, before the X ray, that it was either a surgical instrument or an intestinal parasite.

Mr. MORRIS did not re-examine.

Dr. **ALFRED MARIE VADON**, residing at No. 45 Bd. Victor Hugo, Nice, having been first duly sworn by me, was examined by Mr. MORRIS on behalf of the Plaintiff.

Have you translated Exhibit "A," and is Exhibit "H" your translation?—Yes.

Have you translated Exhibit "F," and is Exhibit "I" your translation?—Yes.

Have you translated Exhibit "G," and is Exhibit "J" your translation?—Yes.

Mr. DICKENS did not cross-examine.

The examination concluded at 5.15 P.M. on the 21st of January, 1930.

[TRANSLATIONS].

Translation of reports of Plaintiff's witnesses examined at Nice, exhibited on taking their depositions as part of their evidence.

Translation EXHIBIT "H."

THE doctors signing below:—Doctor MAESTRACCI, former House Surgeon on the hospitals of Paris, and Laureate of the Faculty, residing at Vence, Twelve Avenue Henri Isnard; Doctor Henry Fay, of the Faculty of Paris, Assistant Surgeon of the Hospitals of Nice, residing at Twenty Rue de la Buffa at Nice, certify that they operated on this day, twenty-seventh September, One thousand nine hundred and twenty-eight, at the Clinique Ste. Marguerite, at Nice, Two Rue Mantega, on Madame Martha Crotch, forty-eight years of age, residing at Vence, Place du Peyre.

General anæsthesia by ether was carried out by Dr. MAESTRACCI.

Mr. ESTAVE, House Surgeon of the Nice Hospitals, acted as assistant to Dr. FAY, who operated.

Median sub-umbilical laparotomy going from the pubis to the umbilicus, circumscribing an old laparotomy scar.

In examination of the abdominal cavity one found first numerous very close adhesions of the small intestines between themselves and of some of them with the vesical dome. These adhesions were so intimate that there appears to be a fusion of the intestinal walls between themselves and with the bladder. In order to liberate them, it would be necessary to open the intestinal and vesical cavities and to carry out multiple resections. In view of such destruction the idea of liberating these adhesions was abandoned and one set to work simply to extract the forcipressure forceps which the X ray photograph revealed to be in the lower half of the abdomen, the point directed towards the small pelvis.

As a matter of fact these forceps could be felt through the agglutinated intestinal loops. But it was impossible to extract it freely because it was surrounded on all hands by the intestines and the opaque membranes which connect these intestinal loops. It appeared to be enclosed in a closed cavity. By oscillating it, it was possible to bring its rings into the field of operation. One then found that the forceps is right inside the small intestine and that it is free in its cavity. It occupies a point in the small intestines which one may locate almost halfway between the duodenum and the ileo-cæcal valve.

At the level of the rings of the forceps, the intestinal wall, forming hernia, has become very thin, distended as it is by the width of these rings.

It was exteriorised as far as possible, and, between two Chaput forceps which raised it, this wall was incised for a length of about six centimetres. Through the opening made in this way into the intestines, it was then easy to withdraw the forceps, which, moreover, came away with the greatest possible ease.

It was thus found that it was absolutely free in the intestinal tube.

However, there existed a frenulum absolutely comparable to a round ligament in appearance and dimensions as to thickness, going from one wall of the intestine to the other, and which passed through one of the rings of the forceps which was thus, as it were, suspended in the interior of the intestinal tube. It was necessary to cut this frenulum in order to be able to withdraw the forceps.

The latter was partially surrounded with fæcal matter, on one of the rings this had accumulated and calcified, forming a veritable fecalome.

Closing of the intestinal incision with linen thread in two planes: one total plane and one sero-serous.

Closing of the abdominal wall in one plane with bronze wire, after having put in place a large rubber drainage-tube, the deep aperture of which answered to the point where the intestine had been opened and sutured.

The extracted forceps, half corroded but still solid, is completely rusted, no longer having any trace of nickel plating. Its jaws are joined, but it is not closed. It measures exactly thirteen centimetres in length. The branches of the forceps are not dismountable, but fixed by a screw.

It is impossible to decipher any mark at all on the forceps.

One can only affirm that it is not a forceps either of Kocher or of Pean.

Besides the old laparotomy scar, Madam Crotch had and still has a long parallel scar on the right costal edge. This scar is due to an operation for cholecystectomy which Madam Crotch underwent at Nice two years ago.

EXECUTED at Nice, on Twenty-seventh September, One thousand nine hundred and twenty-eight.

(*Signed*) D. MAESTRACCI. (*Signed*) H. FAY.

Translation EXHIBIT "I."

Dr. L. PRAT, 24, Avenue des Fleurs, Nice.

On the 8th June, 1926, I operated on Madame Crotch for accidents of acute Cholecystitis. My operation only related to the sub-hepatic region. There were quite a number of vesicular-mesocolic adhesions. The exeresis of the retracted thickened vesicle, which was extremely adherent, was troublesome.

I noted by the symptoms presented by the patient on the level of an old laparotomy scar the existence of a swelling which I considered to be an eventration (illegible) with epiploical adhesions. But the serious hepatic condition of the patient imposed upon me a limitation in my intervention to the vesicular zone and I did not explore the abdomen. The patient shows me to-day a hæmostatic pair of forceps which was removed from her subsequently to an operation from the pelvic region. These forceps, which are considerably rusted, are not of the French model which I make use of. They are in particular with a screw, whereas all my French forceps are hinged and are of the so-called Collin type, which can be taken to pieces.

NICE, 17th December, 1928.

Dr. L. PRAT.

Translation EXHIBIT "J." H.E.81917.

Stamped Paper Frs. 3·60.

I, the undersigned, D. MAESTRACCI, Doctor in Medicine, formerly House Surgeon, Laureate of the Faculty of Paris, do hereby declare :—

That on 12th September, 1928, I examined in my consulting room at 12, Avenue Henri Isnard-Vence, Madame Martha Crotch, 48 years of age, residing at Place du Peyre, Vence.

Madame Crotch came to consult me on account of fearful abdominal pains, re-acting on the bladder, occasioning, with urinary incontinence, an intense discomfort of defæcation, and accompanied by frequent flatulant, abundant discharges in sheets, issuing both from the rectum and the mouth, and at the same time with a persistent metallic taste in the mouth.

Characteristic fact: the pains and flatulant discharges are accentuated in the upright position, or when the patient makes a rather sudden movement, bringing the abdominal muscles into play.

Madame Crotch told me that eight years ago in London she underwent a first surgical operation for multiple cysts on the ovaries, which occasioned total hysterectomy and a second operation for cholecystitis; eight days ago, at Nice, she underwent, without result, three high frequency treatments for vesical polypus. She dates back the origin of her trouble to 1920, a short time, she says, after her first operation.

(Second operation done at Nice two years ago.)

Examination of the Patient.

The abdomen of the patient shows two surgical scars, one sub-umbilical, which is old, trace of the first operation; the other of more recent origin, supra-umbilical, transverse, parallel to the lower edge of the liver, trace of the second operation.

This abdomen is voluminous, distended; notably more voluminous and appearing tumefied at the level of its right half.

On percussion.—One limits on the right an abnormal area of dullness, having a rectangular form, and extending from the hypochondrium as far as the liver.

On the left nothing to point out.

On palpation.—On the right it is exceedingly painful, with resistance of the wall.

On the left, this wall is more supple and mobile; one can easily locate the intestinal loops, whilst it is impossible to do this on the right side, and one remarks that pressing back the flatus on the left side of the transverse colon and of the descending colon causes pains in the right side of the abdomen, which are particularly severe at a point situated a little below the McBurney point and followed by flatulant discharge from the mouth and the rectum which give distinct relief.

On deep palpation.—The bladder and the right ureter are also painful (positive points of Bazil).

One has clearly the impression of an obstacle in the passage of matter with a peritoneal reaction, which is more marked round a point corresponding to the point previously mentioned.

All these troubles are accompanied by fever with general discomfort, generalised abdominal pains, and severe thirst caused by a persistent metallic taste.

Purely symptomatic treatment is prescribed, ice on the abdomen, intestinal disinfection, with appropriate diet, and an X ray photograph is asked for, which was taken at Nice by Dr. Daviot and which reveals a hæmostatic forceps in the small bassin (the negatives are, moreover, in the possession of the patient).

The symptoms not improving in spite of the treatment, surgical intervention is advised.

In faith whereof, I deliver the present certificate to serve for whomsoever it may concern.

EXECUTED at Vence, 15th October, 1928.

D. MAESTRACCI.

CASE FOR THE DEFENDANT.

Mr. RAYNER GODDARD, K.C., for the defence, submitted that the action was barred by the Statute of Limitations, when counsel for the plaintiff argued that plaintiff had shown no lack of diligence, having been to expert after expert to ascertain the reason of the prolonged pain, while, when the forceps were discovered she took immediate action.

Legal points having been discussed, Mr. Goddard stated that Mr. Miles was anxious to be given an opportunity for making a statement, whereupon His Lordship said that decision on the points raised could be postponed until after the evidence was completed.

Mr. Goddard, addressing the jury for the defence, called attention to the difficulties arising out of the lapse of time, such as fallibility of memory, destruction of documents, and death of witnesses; for example, he said, a vital witness for Mr. Miles—namely, the theatre sister at the time of the operation, was among those who had died. He pointed out that since the operation in 1920 a further operation upon the plaintiff had been conducted by a French surgeon at the Belvedere Clinic, Nice, who admitted that in his cases nobody counted the instruments or swabs after operation. Following Mr. Miles's operation the plaintiff had gone from surgeon to surgeon, none of whom had discovered the forceps in the abdomen; whereas, after the operation in Nice the source of the trouble had been detected. He asked the jury to consider it an irresistible inference that the forceps had been left in the plaintiff's body at the second operation. Counsel further said that Mr. Miles did not use forceps of the type found in Mrs. Crotch's body, but when operating in the abdomen he used a completely different type known as "Bulldog forceps," and he emphasised a system which Mr. Miles had devised of using instruments in multiples of three as a guide to the theatre sister in counting them.

At the suggestion of the Lord Chief Justice, Mr. Goddard dealt with the responsibility as between theatre sister and operating surgeon of counting the instruments, and quoted a case, where a swab had remained behind, to show that a surgeon was entitled to rely on the sister in this matter. Mr. Goddard quoted the following case, saying: "In the Supreme Court of South Africa it has been held expressly by the Court of Appeal that a surgeon is entitled to rely upon the sister, and that if the Court is satisfied that he did take reasonable precautions and asked the sister if the count was correct, that then the fact that a forceps is found is not evidence of negligence against him. In the South African case a swab had been left, but I do not know that there is any distinction in law between forceps and swabs. The case is, Van Wyk *v.* Lewis reported in 1924 Appeal Division South African Reports, page 438. May I read the head-note to your Lordship?"

The Defendant, a surgeon, performed an urgent and difficult abdominal operation upon the plaintiff. The operation took place in the hospital at night and the defendant was assisted by an anæsthetist and a qualified nurse on the hospital staff to act as his theatre sister. At the conclusion of the operation one of the swabs used by the defendant was overlooked and remained in the Plaintiff's body, from which it passed after a lapse of twelve months. The evidence showed that in accordance with the usual practice at the hospital the defendant had relied upon the sister to count and check the swabs used, that at the conclusion of the operation he made as careful a search as the critical condition of the patient permitted and that both he and the sister believed that all the swabs were accounted for before the wound was sewn up. *In an action for damages for negligence* in failing to remove the swab, held that negligence could not be inferred from the mere fact that the accident happened but that the onus of establishing negligence lay on the Plaintiff. Further, that although the surgeon performing the operation was bound to exercise all reasonable and proper care as it was a reasonable and proper practice to leave the duty of checking the swabs to the theatre sister the defendant was not guilty of negligence.

THE LORD CHIEF JUSTICE. Did the case end there ?—Yes, my Lord.

MR. WILLIAM ERNEST MILES.

Examined by Mr. RAYNER GODDARD.

Are you a Fellow of the Royal College of Surgeons ?—I am.

Are you Surgeon to the Croydon Hospital for Diseases of the Rectum ?—Yes.

And are you Surgeon to the Cancer Hospital, Brompton ?—I am now Emeritus Surgeon to the Cancer Hospital.

That is a special post which I think was created for you ?—Yes, last year.

Are you, among other appointments, Consulting Surgeon to the Royal Hospital at Richmond ?—I am.

And to various other hospitals ?—Yes.

You are a Fellow of the Medical Society and the Royal Society of Medicine ?—Yes.

And are you the author of various works which are regarded now as standard works in the profession ?—Yes, books and papers.

Have you on several occasions conducted operations at Dr. Wadd's Hydro at Richmond ?—On many occasions.

Were you acquainted with the staff at that Hydro in 1920 ?—Yes.

Did you know the theatre sister ?—Yes, I knew her.

Was she a competent person ?—I thought so.

And had she assisted at several operations for you ?—Before the operation in question, before 1920, yes.

I suppose since November, 1920, you have performed many hundreds of operations ?—Yes.

Do you remember the operation on Mrs. Crotch ?—I have a slight remembrance of it. I cannot remember actual details except in some points, but in some cases an impression is made upon your mind of the features of a case which are, of course, lasting.

What particular feature of Mrs. Crotch's case remains in your mind ?—That the fibroid tumour of her uterus was adherent to the surrounding tissues which was evidence of pre-existing peritoneal inflammation.

Do you remember the patient herself ? Was she a good subject for operation ?—She was stout.

Do you remember anything taking place during the operation, any communication from the anæsthetist about the patient ?—Towards the end of the operation, yes. The anæsthetist said that the patient's condition was such that the operation should be completed as soon as possible.

Why was that ?—Well, the pulse was beginning o fail and the breathing was not too good.

There was a danger of collapse, you mean ?—Precisely.

Before you go down to the Home where you are going to perform your operation how do you arrange your instruments ?—At that time I indicated to Miss Ruddock what instruments I required. I always take the same number of instruments for every abdominal operation, the only variation being special instruments to meet special requirements.

How are your instruments collected together ?—The instruments were all put out, and then I myself saw them and packed them into a special box which I had specially made, a box about 10 inches long, 5 inches broad, and 4 inches deep, and this box was perforated with holes so that it could be used, if necessary, as the tray of a steriliser. With that box I always have the same number of instruments, six small pressure forceps, commonly known as Spencer-Wells, six Cocker's forceps, six Bulldog forceps, nine tissue forceps, then three scissors, and three special instruments, all in threes or multiples of three.

Had you any special purpose or design in thus arranging your instruments in threes or multiples of three ?—Yes, many years ago, at the outset of my surgical career, I devised that method for this simple purpose, as it is commonly known that anyone can count three but not more than three at a glance. Also that if in threes, or multiples of three, any other number shows that it is wrong. Twos, fives, and sevens are wrong; *threes, sixes, and nines* are correct.

You mean at the end of the operation ?—At the end of the operation.

Are surgeons aware that there is danger of an instrument getting concealed ?—Certainly. Cases have from time to time occurred.

And is it to guard against that that you devised this scheme ?—Precisely.

When you get to the scene of the operation what do you do with the instruments ?—Take my bag up to the theatre and then hand over the instruments to the theatre sister. I count the instruments out to the theatre sister and show her that they are in threes and multiples of three.

Does she sterilise them ?—The theatre sister sterilises them and lays them out on the special table relegated for the instruments.

Is that done while you are rendering yourself aseptic ?—Yes, generally washing up and putting on the sterile gown, mask, gloves, and so on.

We have got to the point that you count out the instruments in the presence of the sister. We may go now and follow along the stage of the operation. In an abdominal operation of this description, what is the first step that you take on the patient after he or she is anæsthetised ?—I first of all make the incision. In this case it was from the umbilicus to the pubis in the middle line, what is called a median sub-umbilical incision. It goes through the skin and subcutaneous and fatty tissue first of all. There are three or four bleeding points, as a rule, with that incision. I use Spencer-Wells 5-inch pressure forceps to seize those vessels to enable me to tie them. I generally do the tying and my assistant removes the forceps after the vessel has been tied. Occasionally, if it is more get-at-able, I hold the forceps and my assistant ties the vessel. It may so happen that it is easier for one to do it than the other.

When the vessel is tied what is done with the forceps ?—The forceps are put on one side. Then the next incision is made through the sheath of the rectus, usually in these cases the right rectus muscle. That is a long strap muscle extending from the pubis to the ensiform cartilage and the lower part of the ribs. We avoid, if possible, dividing muscle.

Does bleeding occur in that part of the operation ?—Yes, there may be two or three vessels bleeding there which require picking up with small pressure forceps. Then they are tied and the pressure forceps are removed.

What is the next stage ?—The next stage of the operation is to shut off fatty tissues and the sheath of the rectus muscle. I use Cripps's swabs, and I clip these with what is known as Moynihan towel clips.

THE LORD CHIEF JUSTICE. Is Cripps the name of a man ?

THE WITNESS. The instrument is named after a surgeon inventor. Then you fix those to the sheath of the rectus muscle on either side with three Moynihan towel clips.

MR. RAYNER GODDARD. By the time you come to that are such Spencer-Wells forceps as you have been using removed from the patient's body ?—Everything must be removed in order to enable you to shut off the wound in that kind of way. There can be nothing remaining on the wound that you have already made.

THE LORD CHIEF JUSTICE. Do you mean you could not perform this stage of the operation unless they were removed ?—No, you could not place the swabs in position unless the forceps had been removed. The next stage of the operation is incising the peritoneum, which is bloodless and requires no hæmostasis.

Does that mean stopping the bleeding ?—Yes, my Lord. The next step is to place a self-retaining abdominal retractor.

MR. RAYNER GODDARD. That is an instrument to hold the wound apart ?—Yes, just like my two fingers like *that* pulled apart so as to thoroughly expose the field of your prospective operation.

Are you now in a position to deal with the uterus ?—In this particular case there was a large tumour very nearly about the size of my head. Directly you open the wound there is the tumour in front of you. All intestines have been pushed away by the tumour which arises out of the pelvis.

Do you use or have you ever used in this operation a Spencer-Wells forceps in the abdominal cavity ?—I have been performing abdominal operations for thirty years, and I can say quite emphatically and confidently I have never used a pair of small 5-inch Spencer-Wells forceps in an operation of this kind for the removal of the uterus.

How do you deal in this operation, then, with any bleeding points that may arise inside the cavity ?—In order to remove the uterus there are six vessels to tie. There is an ovarian vessel on either side, an artery and a vein running in the free edge of the broad ligament. Then on either side there is a vessel in the round ligament which is a branch of the deep epigastric artery, and there is on either side the uterine artery which supplies the uterus. I have never placed a pair of forceps on any of those vessels. I under-run each of them with an instrument known as a Reverdin needle-holder, a French instrument and a very excellent instrument. It has an aneurysm needle attachment. You can put a cutting needle or an aneurysmal needle into the holder. For this purpose I use the aneurysmal needle. Passing the ligatures round these six vessels they are thus tied off before the vessels are severed. Therefore there is no bleeding.

THE LORD CHIEF JUSTICE. Would you repeat what you said, beginning with the word "passing ?"—Passing the aneurysm needle beneath these six vessels I withdraw the ligature under each vessel and tie it. Each vessel is tied before it is divided, so that there is no bleeding.

MR. RAYNER GODDARD. Is there any other part of the operation in which you use a Spencer-Wells forceps ?—None whatever.

Do you ever have a Spencer-Wells forceps on the body of a patient who is about to undergo this operation after the peritoneum is severed ?—Never.

You told us about the tying off of the six vesssels in the abdomen. Are there adhesions, do you find, in these cases ?—In a great many cases there are none, but in this particular case there were many adhesions.

How did you deal with those ?—One breaks down adhesions by sweeping one's hand round the tumour. The tumour is generally adherent, or it was in this case adherent, to the pelvic wall. Also there were some adhesions to the omentum, that is a structure hanging from the stomach.

You do that with your hand and without an instrument ?—Yes.

After the uterus and the tubes have been dissected and removed are you ready then to begin to close the wound ?—After the tumour itself has been removed ?

Yes ?—You see, in this operation it has been mentioned that it was a total hysterotomy. That is not my recollection ; it was a sub-total hysterotomy, and a total hysterotomy does not necessarily mean removal of the ovaries. In this case I removed the left ovary and tube because they were matted together with the tumour by old pre-existing inflammation.

THE LORD CHIEF JUSTICE. You say this was not total but sub-total hysterotomy ?—Yes.

Then you went on to add something ?—I only removed, in this case, the left ovary and Fallopian tube.

Did you remove the uterus ?—Yes.

All the uterus ?—Yes, the uterus together, with that Fallopian tube, so that when the uterus was removed all that was left was what is known as the supravaginal surface.

MR. RAYNER GODDARD. Are there two anatomical portions of the body called the round ligament and the broad ligament ?—Yes. The round ligament is embryologically and anatomically quite distinct from the broad ligament. One is a fibro-muscular band.

I only want to know, are the round ligament and the broad ligament two perfectly distinct things ?—Two totally distinct things.

Dr. Maestracci in his evidence referred to the round ligament, and said it was also called the broad ligament ?—He is entirely wrong. I know one of the best text-books in French, Tatu's text-book on Anatomy, and he is very distinct on the point.

It was also said by Dr. Maestracci that he found a portion of this ligament jutting through the ring of the forceps. Will you tell me, first of all, what happened to the round ligament and the broad ligament after the uterus had been dissected ?—The round ligament has very definite anatomical relations. It is attached to the upper part of the uterus immediately in front of and below the entrance of the Fallopian tube. It passes out under cover of the peritoneum between the layers of the broad ligament and leaves the abdomen at a given anatomical point. That anatomical point is the internal abdominal ring, and the internal abdominal ring is a point midway between the anterior superior spine of the ilium and the spine of the pubis.

I want to know what you did with this ligament. That is all I want to know ?—The round ligament is divided close to the brim of the pelvis so that the greater part of the abdominal portion of it is removed with the uterus. The stump, which is never more than an inch in length, is always buried when the peritoneum is sutured, and for this reason, that anatomically the round ligament lies beneath the peritoneum.

You bury it ?—Yes.

And is it sewn down ?—Absolutely.

In the peritoneum ?—Beneath the peritoneum.

And what becomes of what is left of the broad ligament ?—The broad ligament practically does not exist after it has been divided. It is only a double fold of the peritoneum and when you sew its margins together that completes the sewing of the peritoneum.

Is it possible for the remnant either of the round ligament or the broad ligament, anatomically speaking, to have been through the rings of these forceps found where the X ray photograph shows they were found ?—No, for two reasons. One is that when the peritoneum is sewn it is a flush surface, and the free end of the round ligament is buried beneath it. Another reason is that if that round ligament had been through the ring of the forceps the ring of the forceps would have to lay at a definite anatomical point which would be shown five inches lower than it is shown in the X ray photograph.

Would the forceps have been laying with their point down or the point up ?—They could not lie with the point down because, with the ring at that level, you would have to perforate the bottom of the pelvis.

After you have dissected the uterus and sewn up those ligaments does a period come when you are ready to sew up the patient?—Yes. There is the stump of the uterus left which is the supravaginal surface. I use Kocher's forceps and my assistant holds them up so that the stump is brought up out of the depths within reach, and I then sew with a round curved needle.

Is a Kocher's forceps anything like a Spencer-Wells?—Not a bit. These are the forceps invented by Professor Kocher, of Berne, Switzerland. They serve the purpose of a pressure forceps, but they have a tooth at the end so that you can catch hold of a thing and it does not let go. That is Kocher's forceps as distinct from a Spencer-Wells forceps. (*Exhibiting.*)

THE LORD CHIEF JUSTICE. Perhaps the jury would like to see them.

MR. RAYNER GODDARD. May I at the same time hand the jury a 5-inch Spencer-Wells? (*Forceps handed to the Jury.*)

What is the length of the Kocher forceps?—About 5½ inches to 6 inches, I should think. It has a ratchet there. It is very different from the Spencer-Wells; it is to increase the pressure.

Who holds the Kocher forceps?—My assistant.

Who was your assistant in this case?—Dr. Wadd.

THE LORD CHIEF JUSTICE. Two pairs apparently?—Yes, two pairs; one anteriorly and one posteriorly.

And he holds them in that way so as to bring up and expose for sewing what?—To bring within reach the stump of the uterus. We call that the supravaginal surface.

MR. RAYNER GODDARD. Could you perform with Spencer-Wells forceps what you have to do with Kocher's forceps?—No; for two reasons, one that they would be too short to reach, and another that they would slip up because they have not got that spike in the end, and the uterine tissue is very tough.

During this operation what has become of, or what do you do with, the intestine?—The small intestine is packed off into the upper abdomen by means of a Cripps' swab; at least, that is what I use. Some surgeons use a sterile towel; others use a gauze swab. I prefer the Cripps' swab.

Is that something in the nature of a handkerchief or towel?—About the size of a handkerchief, of a special texture.

Who hands you the swabs from time to time?—If there is an assistant nurse in the theatre, then she generally hands the swabs, provided that she is a clean nurse.

You mean a sterilised nurse?—Yes. It is a technical term; clean as opposed to dirty.

One who has been sterilised for the operation?—That is right.

If there is a sterilised nurse present she hands you the towels?—Yes.

Otherwise, who does?—The swabs you mean?

Yes?—The theatre sister if there is no sterilised assistant nurse present.

It is either the nurse or the sister?—Or the sister.

When you get to the stage when you can sew up the patient, what happens?—I make a practice of asking the theatre sister to give me four Kocher's forceps.

THE LORD CHIEF JUSTICE. Do you use the terms "nursing sister" and "theatre sister" as meaning the same person?—The sister and the theatre sister are the same, and the other is generally spoken of as the theatre nurse.

You use now the expression "nursing sister." Who is she?—What I meant, my Lord, was the theatre sister. I ask for four Kocher's forceps, which are handed to me, and usually at that time the theatre sister indicates that she is correct in her instruments; and if she does not, and I do not see for myself—at a glance I can generally tell—then I ask the question if all is correct.

THE LORD CHIEF JUSTICE. Will you mind repeating that last statement?—Usually at that time I ask for four Kocher's forceps. Those are handed to me. At that time the theatre sister usually indicates that she is correct—I mean by that that her instruments and swabs are correct. She may do so in a variety of ways: she may say: "You have a pair of scissors" or "a pair of dissecting forceps," or she may say that she is short of a particular instrument, or more than one. That is an indication to me that she is correct, and if I get no such indication I ask if all is correct.

MR. RAYNER GODDARD. If I heard you aright, I did not quite follow one thing. You said she may say: "I am short of one"?—Yes.

Then you said: "That indicates that she is correct"?—Then I have to find it. Sometimes a thing may get hidden in a towel.

THE LORD CHIEF JUSTICE. And when she says these things which you mention, to whom is she saying them?—She is saying them to me.

MR. RAYNER GODDARD. Can you keep count yourself of the various things that you are using?—No, and I do not attempt to; but with my system of three and multiples of three I can just glance at a thing and see. I know what is happening; at any rate, I know whether the theatre sister is counting the instruments during the operation, which she ought to.

On whom do you rely for the counting of the instruments?—On the theatre sister.

Is that in any way peculiar to yourself, or is that the accepted method in modern surgery?—No. That is the accepted method in all hospitals.

Are theatre sisters trained in this respect?—Very carefully.

In your judgment, would it or would it not be in the interests of the patient if the surgeon relied upon himself to count and check the instruments?—It would be absolutely impossible for the surgeon to go about trying to find or count up instruments.

THE LORD CHIEF JUSTICE. Impossible for the surgeon to do what?—To hunt around for a supposed missing instrument or swab. He would be exposing the patient to greater risk by delaying the operation.

MR. RAYNER GODDARD. But if the instrument is reported as missing, what do you do then?—Then it has to be looked for. Then I have to satisfy myself that it is not inside the abdomen.

Could you check the instruments yourself—I do not mean necessarily hunt round for a missing instrument, but at the close of the operation when the patient is ready to be sewn up would it be in the interests of the patient that you yourself should check with your own hand the instruments?—No, it would delay matters.

THE LORD CHIEF JUSTICE. Does it really then come to this, Mr. Miles, that if the theatre sister says that the number is correct you act upon that statement?—I am quite satisfied.

MR. RAYNER GODDARD. After the patient has been put to bed do you pack up your instruments yourself, or do the nurses do it?—The nurse in the theatre generally washes them; then I have them put out after they have been washed and dried; I myself pack them into my receptacle. In doing so I always count them to see that they are correct.

Have you ever found in the course of your surgical career that your instruments were not right?—I have never missed a pair of forceps—never in the whole of my existence—that is, surgical instruments.

When you get home after an operation to whom do you give your instruments?—Miss Ruddock. Up to about 1925 she used to do this; but that includes 1920. Up to that time she unpacked my bag, took out the instruments, laid them on the table so that I could see them before they were put away, and she counted them.

That is the same lady who packed the bag?—Yes.

You have been telling us, as I understand, about your usual practice in operations. Are you able to say, one way or another, whether you carried out that routine that you have told us of when you operated on Mrs. Crotch?—It is very difficult to remember details of what you did ten years ago, in just the same way as I cannot tell you particularly whether I shaved first or had my bath first on any particular day; but

I usually have a bath and I usually shave, and I am perfectly certain that on any day during the last ten years I have done both. I can only say that I probably carried out the routine which I generally adopt, but specifically I cannot remember each individual instance.

Are you able to say, one way or another, definitely whether you were short of forceps after the operation?—I can say that absolutely definitely.

That you were not?—That I was not.

Did you see Mrs. Crotch in the nursing home before she left?—That is, after the operation?

Yes, after the operation?—Yes, I may have seen her two or three times. I do not know.

Is there anything that remains in your memory, as to whether you can say that the convalescence was other than normal?—I can speak of her convalescence as uninterrupted.

Do you remember anything more about it than that?—Nothing whatever.

Do you as a rule desire to see your patients after they have left the nursing homes?—I always request the patient or request the doctor to ask the patient to see me after an operation at the termination of the convalescence. That is usually done when they have gone down to the sea for three or four weeks; after their return I wish to see them, especially after an abdominal operation, and I like to see them for the express purpose of seeing whether their scar is sound.

You know Mrs. Crotch came to you on the 10th May, 1921?—She did.

Was that earlier or later than you expected to see her?—Very much later, because I had arranged with Dr. Wadd that she should come at the termination of a three- or four-weeks' convalescence.

Did she give you some explanation of the delay? You need not go into it?—She had some domestic trouble.

What recollection have you of your interview with her in May, 1921?—When she came to my house, of course I sent her into the derobing room. Next to my consulting room is a small room with a couch where a patient can get undressed. After the preliminaries of conversation I sent her in there. I am quite certain, although I cannot actually remember it, that I examined her. I always put patients through definite tests.

She said you made her cough?—Yes. I do everyone. To see whether the scar is sound. I say "Cough," to see whether there is any herniation.

We know from Dr. Stevens, who saw her in the following September, that at the time he saw her there was a hernia?—I heard him say that.

So far as you have any recollection, was there any hernia when you saw her?—To the best of my recollection there was none; and I say so because if there had been I should have immediately reported it to Dr. Wadd, whose patient Mrs. Crotch was; she was not my patient beyond the fact that I operated on her. She was his patient.

You mean that she is your patient for the operation. After that she is the doctor's and not the surgeon's?—Yes. After that I had finished, and she had no right to come to me without Dr. Wadd, unless he sent her.

I think the Plaintiff said in her evidence that you told her that the lump——

THE LORD CHIEF JUSTICE. What she said was this, Mr. Rayner Goddard: I will read it to you: "I came to see the Defendant in May, 1921. I told him I was seedy and worried, and could not understand why I had the lump; and he said to me: 'Well, let us have a look.'" Have you any recollection of that?—I have no recollection at all of her saying anything about a lump.

Then she said this: "He examined me thoroughly, saw the lump, pressed it, made me cough several times, and then said: 'Now, don't worry; you will not need to have another operation'; and that because I had expressed the fear that I might have to undergo another operation. He said that the cause of the lump was some injury in the course of the operation of the muscle of the abdomen, and that I need not worry." Have you any recollection of that?—No recollection at all. I cannot conceive that I should say that she would have an injury to the muscles of her abdomen, because it would have been absurd.

Then she went on to say: "I said: 'You are certain that I have not got another growth,' and the Defendant said he was certain. 'I cannot see,' he said, 'how you can possibly have another growth, as there is nothing for it to grow to.' He said that I had not had a fair chance since the operation, and that I would get well with rest and care. I think he prescribed some medicine. My mind was relieved. He said that I must not expect to get over an operation of that kind in less than a year." Do you recollect any part of all that?—No. I cannot recollect the details of the conversation, but I am quite certain I never said that there was nothing for a tumour to grow to, because that would have been an utterly ridiculous thing to say. If I said anything of the kind I should have said: "nothing to grow from," not "nothing to grow to."

Can you say aye or no did you see a lump?—I have no recollection whatever of seeing a lump. I am quite positive about that.

MR. RAYNER GODDARD. Did you write to her doctor?—I believe I telephoned to Dr. Wadd; I do not think I actually wrote to him, but I think I telephoned him to say that I had seen Mrs. Crotch.

Supposing there had been a lump there, what would have been the treatment you would have ordered?—First of all, I should have formed an opinion as to the character of the lump. The most likely thing would have been a hernia.

Assume that it was, as Dr. Stevens said he afterwards saw, a hernia; what treatment would you have given?—Then I should have suggested wearing a truss or a belt.

Do you agree with Dr. Stevens that this is a common thing after abdominal operations?—Very often, after an abdominal operation on a fat subject. Surgeons differ from ordinary mechanics. We have to deal with what we are given, what the patient provides us with; we do not choose it like the man who makes a house.

Is there any danger in the hernia?—Not unless it becomes big and becomes strangulated. If there is a hernia you use a truss to protect it, because you might get a strangulated hernia.

THE LORD CHIEF JUSTICE. What is a strangulated hernia?—When a portion of the intestine thrusts itself through a small opening, and the neck of the opening becomes tight and cuts off the blood vessels—strangulates them.

MR. RAYNER GODDARD. Dr. Stevens told us that in September of 1921, when he was consulted by this lady and found that she had got this lump, she was also complaining of some pain in the lower abdomen. Would that surprise you?—I do not see why she should, because there was no connexion between the ventral hernia and pain in the lower abdomen particularly.

Is there anything after an abdominal operation which may cause any pain in the patient from time to time?—Sometimes adhesions. Now this patient had very extensive adhesions to her uterus, which, as I said, was evidence of pre-existing inflammation. She probably may have got adhesions to the part where the adhesions were separated. That is a very common thing to have.

At any rate, there was no further reference of the patient or by the patient to you?—None whatever.

You remember, I think, that a friend of hers came to see you in July, 1924, but have you any recollection of her coming with the friend?—Mrs. Crotch either wrote or telephoned—I cannot tell which—that she wished to bring a friend of hers to consult me, and she did bring the patient. She brought the patient to my present address. I examined the patient and she paid her fee, but I did not examine Mrs. Crotch.

Mrs. Crotch, I think, says that she did not say more than that she was seedy——

THE LORD CHIEF JUSTICE. What she said was this: "Incidentally, the Defendant said to me: 'You do not look very well; you look very poorly,' and I said, 'Oh, I am always seedy.' He examined my friend and told me she had cancer. This alarmed me because of my own state, but he said to me, 'Don't you worry; you are all right.'" Do you recollect anything of that?—No, I do not recollect the details of that.

THE LORD CHIEF JUSTICE. She went on to say: "I did not ask him to look at my lump, nor did he."

MR. RAYNER GODDARD. I want to ask you now about two or three matters which have arisen from what you have heard of the medical history since 1921. She has told us that when she went to India she had dysentery?—Yes, I heard that.

And, I think, malaria. So far as you can speak, could the presence of a foreign body in the intestine have caused dysentery?—Certainly not. Dysentery is due to a definite amœba.

What is that—a germ?—It is an organism.

Could there be any connexion between dysentery and gall-bladder trouble?—Oh, yes. Dysentery leads to an ulceration of the rectum and colon, chiefly the rectum, and you may get as a sequel to that gall-bladder inflammation, cholecystitis—quite a well-recognised possibility.

THE LORD CHIEF JUSTICE. Although the presence of forceps might not directly cause dysentery, might they set up an internal condition which in its turn might develop into dysentery?—I do not think so, because dysentery is a specific disease.

MR. RAYNER GODDARD. You have heard also Dr. Prat's evidence that when he operated on the bladder for gall-stone he noticed at the site of your operation a swelling which he took to be a hernia of some sort?—Yes.

Is that consistent with Dr. Stevens's evidence in your opinion?—I think so—probably one and the same thing.

Would forceps in the intestine where you know they were found be indicated by a lump—I mean the sort of lump which Dr. Prat described? Can you form any opinion upon that?—I can imagine that a pair of forceps among the intestines would produce a tumour.

A tumour?—A tumefaction, at any rate.

THE LORD CHIEF JUSTICE. A swelling?—Yes.

MR. RAYNER GODDARD. Would that be an external swelling like hernia?—Oh, no.

What would be the difference?—It would be inside the abdomen among the intestines: it would not be extruding through the abdominal wall like a hernia.

How would you discover it; by palpation or by observation?—You mean to discover a pair of forceps in an abdomen?

Yes?—By X rays.

THE LORD CHIEF JUSTICE. "Palpation" means handling, does it?—Yes, feeling in *that* way (demonstrating).

MR. RAYNER GODDARD. Would you see anything on the outside or would you have to handle the patient?—No; you would have to palpate very carefully. If they were deeply down in a fat abdomen you would not feel anything at all.

Would you deal with one matter. (X ray photograph and chart handed to the Witness.) Has Dr. Fay marked the position of the forceps in accordance with the position shown in the X ray photograph?—That is on the diagram?

Yes?—Yes, he has marked it there.

Does that correspond with the X ray photograph?—No. Where he has marked it the forceps lie longitudinally and parallel to the middle line, whereas in the X ray they are obliquely placed and to the right. *This* is dead in the middle line parallel with the middle line.

The X ray photograph—the other photograph—of course, shows them underneath the incision made by Dr. Prat?—Yes, on the right side.

There is no question from that photograph that they are in the neighbourhood of the scar that your operation made, is there?—Yes, they are in the abdomen and not in the pelvis. What we call the pelvis is what the French call "le petit bassin," and they are not in "le petit bassin," according to that photograph.

How do they lie in relation to the area with which you dealt?—My incision would be running along *there* in the middle line, and those forceps are well to the right of the middle line. (Demonstrating on the X ray photograph.)

You have just shown us where your incision was. Where is Dr. Prat's mark?—*That* is Dr. Prat's mark across *there*, and mine is straight down the middle line (indicating).

(To be continued.)

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. F. W. Chippindale to be Surg. Sub-Lt.

Surg. Sub-Lt. F. W. Chippindale to be Surg.Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. Storrs, having attained the age for compulsory retirement, is placed on ret. pay.

Maj. and Bt. Lt.-Col. F. D. G. Howell to be Lt.-Col., vice Lt.-Col. R. Storrs to ret. pay.

ARMY DENTAL CORPS.

Lt. R. G. J. Tovey resigns his commn.

TERRITORIAL ARMY.

Lt. D. S. Middleston to be Capt.

Second Lt. C. A. Lindsay (late M.G.C. (Infy.)) to be Lt.

R. Coyte (late Surg. Lt., R.N.), to be Lt.

ROYAL AIR FORCE.

Air Commodore J. McIntyre is appointed Director of Medical Services, Air Ministry.

Flight Lt. R. Thorpe is granted a permanent commission in this rank.

Flying Officer P. B. L. Potter is promoted to the rank of Flight Lt.

Maj. A. A. McMullan (Army Dental Corps) is granted a temporary commission as a Squadron Leader (Dental) on attachment to the R.A.F.

Flight Lt. S. A. McCormack (Capt., Army Dental Corps) relinquishes his temporary commission on return to Army duty.

DEATHS IN THE SERVICES.

Surgeon-Major Alexander Gamack, an old Hon. East India Company's servant and retired member of the Indian Medical Department of the Indian Army, died at his residence at Hampstead in his 97th year on March 8th. The son of William Gamack, a solicitor, of Peterhead, Aberdeenshire, he received his early education at the Academy in that town and later entered at the University of Aberdeen where he graduated M.D. in 1854. In 1856 he became a licentiate of the Royal College of Surgeons of Edinburgh and in the same year joined the H.E.I.C. and became assistant surgeon, reaching the rank of Surgeon-Major after some 20 years' service. He was for a considerable time zillah surgeon and jail superintendent at Madura.

The Air Ministry announces the appointment of Group Captain Henry Cooper, D.S.O., an Honorary Surgeon to the King on relinquishment of this appointment by Air Vice-Marshal David Munro, C.B., C.I.E., who has retired.

POST-GRADUATE COURSE AT WITWATERSRAND UNIVERSITY.—On Feb. 3rd 100 South African doctors arrived at the Medical School of Witwatersrand University, Johannesburg, for a post-graduate course. The course opened with an address by Prof. Raymond Dart and consisted of lectures addressed to practitioners and district surgeons. The course for district surgeons included lectures on public health, hygiene, medico-legal, and post-mortem work. The Union Government has taken an interest in the course and has paid the fees of district surgeons attending as well as providing them with railway travelling warrants. Many more applications were received for the course than could be accepted.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

New Departures in Health Administration.

AT a recent meeting of the Edinburgh branch of the Institute of Public Administration, Dr. Parlane Kinloch, chief medical officer for the Department of Health, gave a lecture indicating the new developments in health. The effect of the health services in their environmental and curative aspects was illustrated, he said, by a reference to the gradual lengthening of the average span of life from 20 years in the sixteenth century to under 25 years at the close of the eighteenth century, 47 years in 1910, and 56 years in 1928.

"Consider," said Dr. Kinloch, "exactly what the figures mean. They mean, of course, first, that since the beginning of the nineteenth century the average span has been more than doubled. But they mean much more than that. They mean also that life is more vigorous for our people as a whole. Do not be misled by scaremongering articles about interference with nature's laws of the 'survival of the fittest.' What the short but triumphant story of public health reveals is that if we knew enough and could apply what we knew, all children born might survive to a healthful life and a good old age. As it is, with imperfect knowledge imperfectly applied, we can approach closer and closer to that ideal."

He indicated also how the family practitioner, who was still the backbone of medical service, could be brought into organic contact with the new health machinery. A comprehensive domiciliary medical service for the general population might best be obtained by extending the insurance principle to the dependants of insured persons, and possibly also to classes of people like the small shopkeeper who had not hitherto come within its scope.

I learn that plans are afoot for bringing into closer relationship with the public services the whole work of the approved societies. Hitherto the gap between the public medical services and the societies has been very badly bridged. Plans are being considered for a more effective rapport between the available services and the approved societies as well as the insurance committees. It would be very strange if these complicated organisations remained unaffected by the new system of public medical organisation.

Scotland and Medical Education.

The Medical Register for 1930 and the Medical and Dental Students' Register contain some interesting figures. They bring out in a striking way the great proportional part played by the Scottish medical schools in medical education. The peak both in England and in Scotland was reached in 1919, when 1375 students registered in England and 1387 in Scotland. For the ten years following, England's figures were: 1099, 833, 946, 210, 390, 496, 577, 503, 544, 630. Scotland's were: 910, 602, 587, 243, 435, 410, 494, 539, 577, 626. In the totals for the years from 1905 to 1929, England has 16,473, or 41·8 per cent., against Scotland's 14,951, or 37·9 per cent. Since 1923, the low water mark, Scotland has in each of three years actually exceeded England. In 1929 the two countries are nearly equal—630 against 626.

At the graduation end of the curriculum the Scottish proportion is not so great; but even here the smaller country much more than holds its own. On the average of the 20 years ending 1929, 694 graduates entered the English Register; 471 the Scottish. Here Scotland has nearly 68 per cent. of England's figure. In the last five years the average registrations for England were 973 against Scotland's 504, which, however, is about 52 per cent. Again, in 1930, the total on the Medical Register as at Jan. 1st is 54,870. Of this total, 26,314, or 47·9 per cent., entered by the English Register; 17,198, or 31·3 per cent., by the Scottish. This is a substantial preponderance for England; but then England has a population of some 36,000,000; Scotland has not quite 5,000,000.

Population has, perhaps, no very direct relation to medical graduates; but it is at least interesting to note that, while Scotland's registrations are about 3·4 per 1000 of the Scottish population, England's are only 0·73 of the English population.

An Exhibition of Health and Hygiene.

The second Edinburgh health exhibition, promoted by the City of Edinburgh and organised by the medical officer of health, has been opened by Mr. Watson, solicitor-general for Scotland, acting as deputy for the Secretary of State. The Lord Provost took the chair, and the Waverley market was well crowded for the whole afternoon. At the exhibition two years ago, some 120,000 people passed through in the course of ten days. This year's exhibition is to be open for 16 days and, to judge by the popular interest, the previous numbers will be far exceeded. One of the chief attractions is the child welfare section, where one can see a day nursery at work, with infants being fed and managed; an ultra-violet ray section with children undergoing exposure; a day nursery in full activity, and demonstrations of remedial massage. The Edinburgh mothers made a large crowd in this section. They were also keenly interested in the demonstrations of cookery, where working women were cooking their food with working-class fires and appliances. There is an admirable exhibit of foods and they attract much attention. There is a section for irradiated milk, a section on venereal diseases arranged by the British Social Hygiene Council, and an admirable exhibit by the Dental Board. Agriculture is represented by real cowsheds and real cows. Among other striking objects on view are a waterfall, illustrating a modern electric power plant, and a "slum" kitchen and stair-head, which is a masterpiece of realism. The City Corporation deserve the thanks of the whole community of South-Eastern Scotland for this extraordinarily effective effort in health propaganda.

A point made by the Solicitor General in his address was that there should be a closer contact between the experimenting and thinking mind of the medical schools and University, and the trained minds and exhaustive records of the public health department. If there was that collaboration, the experience garnered by the public health department could be used to direct and guide the line of inquiry and practical thought of the academic mind; the experimenting of the academic mind could be tested in the organisation of the public health department.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

A Medical Society Educates the Public.

AT the recent annual joint meeting of the medical societies of New York, Pennsylvania, and New Jersey a full report was presented of popular educational work carried out during the last four years in the last-named State. The work began when a medical executive secretary was appointed by the State Medical Society, one of his several assigned tasks being the inauguration of such a campaign. He began by educating the legislators regarding the claims of cultists—work which is said to have borne good fruit. At the same time lectures were given to lunch clubs such as Rotary and Kiwanis. In the second year the speaking campaign was extended to radio and since then regular 15 minute talks have been broadcast. Copies of broadcast addresses were syndicated to the press. Response to the radio speeches came from as far East as Scotland and as far West as San Diego. In the third year a new factor was added by the formation of the Women's Auxiliary to each county medical society. These societies help (1) by self-education in study groups; (2) by the promotion of the public education campaign of the medical society; (3) by gifts of dressings and appliances to hospitals and patients; and (4) by securing or donating subscriptions to *Hygeia*, the popular health magazine of the American Medical Association. For the last three years the medical secretary has been assisted by a lay woman who has given all her time to health education. During the year 1928-29 76 addresses were given to an aggregate audience of 6250. Last autumn the campaign entered the schools and in two months (November and December, 1929) no less than 13,288 pupils were addressed.

Untruthful Advertising.

The National Better Business Bureau has made public a stipulation obtained by the Federal Trade Commission from an unnamed corporation selling and distributing cigarettes and other tobacco products. In this document the corporation admits the use of testimonials for advertisement, obtained from "famous people" for a "valuable consideration," to the effect that the products "protect from irritation." The advertisement also contained a testimonial or endorsement supposedly by certain actresses that they remained slender by the use of these particular cigarettes, when as a matter of fact the actresses in question do not smoke cigarettes at all. A statement was broadcast over the radio purporting to come from a well-known musical comedy star and saying that he used these cigarettes when making a certain talking picture. Although he received a consideration for this statement, he had not prepared it or seen it prior to its use. The corporation agrees to state in future when its testimonials have been paid for, this statement to be published conspicuously with the advertisement. In future, also, the corporation will refrain from advertising such statements as "Women retain slender figures" and "Overweight is banished." They also agree that if they should ever resume any of these questionable practices the signed stipulation of facts may be used in evidence against them.

The Control of Venereal Diseases.

Surgeon-General H. S. Cumming recently made a report to Congress on the control of venereal diseases in the United States. This he regards as being still one of our major public health problems. In spite of the decrease in prevalence that has taken place since the world war there are constantly under treatment or observation by physicians approximately 474,000 cases of gonorrhœa and 643,000 cases of syphilis. It is estimated that 697,000 cases of gonorrhœa and 423,000 cases of syphilis seek treatment for new infection in the course of a year. The Public Health Service has sought to control the spread of these infections through coöperation with State and local health authorities by educational work and by research. A recent investigation concerned the incidence of syphilis among negroes in the southern rural districts. A campaign has also been launched for the prevention of venereal disease in the American merchant marine. The Public Health Service is coöperating with the Health Section of The League of Nations.

The Psychoneurotic Aspect of Heart Disease.

At a recent meeting of the New England Heart Association Dr. J. A. P. Millet discussed the problem of psychoneurosis in heart disease. Security is a fundamental need. When it is threatened the patient goes through doubt, fear, and obsessions to anxiety. The heart gives often alarming evidence of its failure to function normally. Therefore the physician must be definite in his prognosis. Any uncertainty that may appear in his mind will be multiplied ten times in the mind of his patient. Too much exercise must not be permitted, but restrictions should not be unnecessarily severe or the patient's anxiety will be increased. The understanding of the physiological basis of his symptoms will often be helpful to the patient. Reports of cured cases will add to his assurance.

Public Health Services.

SCHOOL MEDICAL SERVICE.

—	Number on roll.	Average attendance.	Routine inspection	Special and re-inspection	Percentage of defects.
Taunton	2816	2595	955	2994	14·7
Torquay	3880	3384	1411	5661	23·5

Taunton.

THE school dentist's report which opens the year's review of school medical work at Taunton contains some satisfactory facts and figures. As Mr. A. J. Percy, L.D.S., remarks, it frequently happens that parents are more fearful of dental treatment than the children themselves, and it is encouraging that more and more parents are attending the clinic with their youngsters; the proportion of appointments kept (75 per cent.) is also quite good. The ratio of fillings to extractions of permanent teeth was over 4 to 1. In the general medical report it is seen that coördination is at its maximum, for Dr. John Allen is at once medical officer of health, school medical officer, and medical officer for maternity and child welfare, while the school nurses also act as school attendance officers. Taunton has the advantage of being the site of the orthopædic clinic of the Somerset County Council, and the council's tuberculosis dispensary is open to Taunton cases every Monday. In elementary school equipment improvement is urgently needed, for a supply of drinking water is lacking in several schools, while others still have trough closets. The fact that so many schools had to be closed on exceptionally cold days suggests that the heating arrangements are none too good. In regard to treatment, Dr. Allen gives a list of agencies through which parents may obtain help for their children. An unusually large percentage (3·7) of children were found to need treatment for tonsils and adenoids; most of these obtained it for the most part independently of arrangement with the hospital. The orthopædic clinic with its specialist surgeon, sister and voluntary helpers, continues to do good work. There are no special schools of any kind in the borough, but several children have been sent to residential schools outside. Dr. Allen writes interestingly on the mentally defective and the recommendations of the Departmental Committee. "Certification and notification (when necessary) is now only possible," he says, "for children from 7 to 14, and in some cases up to 16." It would be more exact to say that children under 7 cannot be compelled to attend special schools; they can do so if the parents are willing and if the schools are available, or they may be dealt with under the Act as feeble-minded and neglected. In his list of conditions under which an adolescent defective can be dealt with, he omits alleged "neglect," a section which is not interpreted with unreasonable strictness. But that many difficulties arise from the absence of special school accommodation is only too true.

Torquay.

Dr. T. Dunlop mentions the increasing need of assistance for the one school nurse on account of the extension of the borough, and Dr. J. V. A. Simpson notes that a new school is being built in the region of the new housing scheme which will conform to the high standard maintained in the borough. It is not always realised how far-reaching is the importance as an educative force of the hygiene of school buildings. Much is being done in Torquay for the pre-school children; treatment is open for them at the school clinics, including operations for tonsils and adenoids, and (especially valuable) treatment for early squint cases by glasses and fusion training. The orthopædic scheme also takes in pre-school children, and they are included in the dental provision; it is hoped to get each infant at the welfare centre to the dentist for inspection, and treatment, if necessary. Tribute is paid to the school nurse, Miss Highes, and a chart shows how the percentage of unclean heads has fallen from 30 in 1908 to 2 in 1929. Arrangements have been made for dealing with tonsils and adenoids at the Torbay Hospital; the children are kept in hospital for about a week, and full provision is made for after-care. Dental work is satisfactory; only 106 permanent teeth were extracted on account of decay, compared with 3028 fillings—a ratio of nearly 30 to 1 in the right direction. The percentage of genuine objectors is only eight, and it is felt that this figure could be lowered by special efforts on the part of the teachers; in one school the percentage availing themselves of the facilities offered was 78, in another it was only 52. Nineteen per cent. promised to obtain treatment privately, but the promises were not always honoured. The condition of the teeth in the Grammar School children was not as much above the average as might have been expected. Excellent work is going on at the open-air school, at which also rheumatic heart cases are cared for; this school also deals with some crippled children who would elsewhere go to a special school. With the full orthopædic scheme in operation it may be hoped that one day crippled children will be rarities, crutches and irons "relics for museums." An appendix contains an account of Dr. Simpson's further work on the measurement of physiological efficiency with the Woolham-Flack methods, special emphasis being laid on the results of repeated tests; an unstable "wobbling" type occurs among the less fit. In practice the tests were found useful in selecting the boys to be allowed to swim.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 8TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 393 (last week 439); scarlet fever, 2601; diphtheria, 1720; enteric fever, 37; pneumonia, 1885; puerperal fever, 73; puerperal pyrexia, 114; cerebro-spinal fever, 17; acute poliomyelitis, 7; acute polio-encephalitis, 3; encephalitis lethargica, 14; dysentery, 34; ophthalmia neonatorum, 117. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on March 11th–12th was as follows:—Small-pox, 594 under treatment, 26 under observation (last week 602 and 23 respectively); scarlet fever, 2146; diphtheria, 2745; enteric fever, 13; measles, 1018; whooping-cough, 80; puerperal fever, 21 (plus 12 babies); encephalitis lethargica, 123; poliomyelitis, 1; "other diseases" 19. At St. Margaret's Hospital there were 8 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (0) from enteric fever, 152 (59) from measles, 8 (4) from scarlet fever, 51 (7) from whooping-cough, 48 (12) from diphtheria, 42 (12) from diarrhœa and enteritis under two years, and 88 (12) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Huddersfield, Bradford, Sunderland, and Newport (Mon.). Fatal cases of measles were concentrated at Portsmouth and Manchester each 12, Sheffield 9, West Ham 6, Blackburn 5. (Glasgow also reported 13 deaths.) Whooping-cough claimed 7 victims at Birmingham, 4 each at Middlesbrough and *Newcastle-on-Tyne*. No large town reported more than 3 deaths from diphtheria. Manchester reported 6 deaths from diarrhœa, Birmingham 4. The highest figures for deaths attributed to influenza were Hull 4, Brighton, Birmingham, Liverpool, and Middlesbrough each 3.

The number of stillbirths notified during the week was 203 (corresponding to a rate of 41 per 1000 births), including 41 in London.

Correspondence.

"Audi alteram partem."

ÆTIOLOGY OF DISSEMINATED SCLEROSIS.

To the Editor of THE LANCET.

SIR,—For several years I have thought that the *functional efficiency of the liver* is impaired in disseminated sclerosis, and in this respect my observations confirm those recorded by Miss Kathleen Chevassut in her important and interesting paper published in THE LANCET for March 15th. There is no doubt that the disease is often aggravated by childbirth, and sometimes its apparent onset or more frequently the occurrence of a period of activity is the immediate sequel of parturition. Dr. Gordon Holmes has noticed a similar result follow operations, even of a trivial nature. The common factor in childbirth and operations is the frequent use of chloroform, a well-recognised hepatic poison. I have also been impressed with the greater frequency of toxic symptoms following the injection of organic arsenical preparations in disseminated sclerosis than in other diseases, such as tabes. These observations led me to investigate the lævulose test in a small series of cases of disseminated sclerosis, and in the majority a slight but definite hepatic insufficiency was discovered. In one case the blood also gave an indirect van den Bergh reaction.

Apart from the possible connexion of hepatic insufficiency with the *Spherula insularis* described by Miss Chevassut, its presence is an indication that twilight sleep should be employed in place of chloroform when a patient with disseminated sclerosis is in labour, and that if an anæsthetic is required for any operation chloroform should never be used.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, March 16th, 1930.

THE DRAFT POOR LAW ORDER.

To the Editor of THE LANCET.

SIR,—It is a little disappointing to find THE LANCET commending an Order which tends to establish and entrench the existing system of poor-law administration just at the time—indeed the only favourable time—for breaking away from it. It is difficult to imagine a more inaccurate description than your word "modernisation" for this anachronism. You point out yourself that the opportunity has been taken, as in Article 19, to generalise some of the duties of the Guardians which were formerly prescribed in detail, and it should also be noted that the Ministry have issued, on Feb. 11th, Draft Rules and Orders in relation to relief which materially change the old position. As regards officers, however, the Draft Order prescribes duties and conditions of service which may have been necessary and desirable sixty years ago, but which are not only out of date now but thoroughly objectionable under what was hoped to be a new system of administration. It is not too much to say that if the Draft Order in its present form became statutory some of the reforms which the whole medical profession have considered desirable could not be brought into effect.

The view of the Ministry of Health, I believe, is that there must be the least possible amendment of the old Orders until they have time to consider in collaboration with the new authorities what vital changes ought to be made at a later date. I suggest that in the present instance this is the wrong way to approach the subject. In these matters there is definitely a tide which has to be taken at the flood, and there is grave danger that the determination of the Ministry that the transfer of poor-law administration shall be carried out smoothly at all costs, may result in such an establishment of the bad features of the existing system that it will be very much more difficult a year or two hence to bring about locally changes which would now be accepted by the authorities and which the medical profession desire. It is wrong to say that "no medical officer of health or medical practitioner will find himself any the worse." If a change which was recognised to be more or less revolutionary, and which was threshed out for years before it was brought before Parliament and then established by statute and accepted by the public and its representatives, is found to be, in fact, no change at all, those who were supposed to be affected by it are in a weaker position than if the change had never been proposed.

I am, Sir, yours faithfully,
RALPH M. F. PICKEN,
March 15th, 1930. M.O.H. and School M.O., Cardiff.

THE MISSIONARY DOCTOR IN INDIA.

To the Editor of THE LANCET.

SIR,—I venture to ask the hospitality of your columns for a quotation just received from a young missionary doctor in India which will, I think, prove of interest to many newly qualified men and women. Dr. Ruth Bocock writes in her annual report:—

> "As I sit down to write this report there is one question uppermost in my mind, and this is, 'Why is it so hard to find a sufficient number of doctors to supply the needs of the mission field?' There are many answers, I know, to this query, but I am sure that one is that many people at home have a mistaken idea as to the conditions of medical work prevailing in India. When I first came out here, just three months after leaving my last English hospital, I did so with many misgivings. I was thoroughly in love with my work at home and very keen on all the latest advances and such like things. I had it well rubbed into me by all sorts of people that I was very foolish to throw up work in England, that the privations out here would be great from a medical point of view, and that the medicine I should have to practise would be very simple. My misgivings soon vanished into thin air; the routine in the hospital here I found to be very similar to that at home, and the diseases in many ways more varied and interesting. In less than a fortnight I found myself quite at home and realised that people who talk of doctors throwing up their careers by coming to India are very ignorant people."

Similar testimony could be borne by many from other countries as well, and the secretaries of any of the missionary societies in this country will be glad to hear from young doctors who wish for a very fine scope of service as a witness to the Christian faith.

I am, Sir, yours faithfully,
HUGH H. WEIR,
Secretary, Medical Missions Department, Society for the Propagation of the Gospel.
15, Tufton-street, S.W. 1, March 5th, 1930.

TENNIS ELBOW.

To the Editor of THE LANCET.

SIR,—I should like to congratulate Dr. Marlin on his brief yet very comprehensive paper in your issue of March 8th (p. 509). It seems to cover the whole ground on "Tennis Elbow" very effectively both as regards pathology and treatment, the former being largely hypothetical because of its varied causation. For the same reason the treatment is by no means stereotyped. In the typical tennis elbow which, in my judgment, is a fibrositis of the fascial attachment of the supinators to the external epicondyle of the right arm, and the typical golf elbow which is a fibrositis of the facial attachment of the supinators to the external epicondyle of the left arm, the treatment par excellence is manipulation. This consists in a hyperextension of the elbow joint, and is usually effected by a sudden movement at a single sitting without an anæsthetic. When this happy result fails to supervene, the case is not typical and is complicated by some other factor such as rheumatism, gout or traumatism. It is in such cases that diathermy, radiant heat, static electricity, or sometimes even surgical intervention is required.

I cannot help expressing the greatest surprise at the continued apathy of the medical profession in connexion with the subject of manipulative therapeutics. I know not whether I have been endowed with more than my share of tactile sensation, but I do know that from the very beginning of my medical career, close upon half a century ago, whenever I failed to cure a patient with the ordinary medicinal and other remedies, I always endeavoured to effect a cure by the use of my hands, not infrequently with excellent results. I am not at all surprised at the success claimed by the so-called osteopath in many cases which have baffled the regular medical practitioner, because the latter deliberately fails to recognise or even look for the real cause of the trouble. I have a strong suspicion that the average medico regards it as infra dig to use his hands on a patient. He confuses manipulation with massage, which he regards as a menial occupation only to be relegated to the bath attendant or other type of unsophisticated person. And yet, in THE LANCET of March and April, 1871, Wharton P. Hood, M.D., M.R.C.S., gave a description of what was commonly called "bone-setting." And we must never forget that it was four years subsequent to this date when another fully qualified medical man laid the foundation of the so-called science of osteopathy, which he claimed to be the only rational system of medicine.

Elsewhere[1] I have controverted this idea.

> "If it be a system of medicine, at the best it is purely a system of one idea. Its nosology is a lesion; its symptomatology, a subluxation; its therapeutics, manipulation; whilst its pathology is accommodating enough to cut both ways, the subluxation being either the cause or the effect of departure from function. . . . Despite these limitations, however, as a method of treatment it serves a useful purpose not only in emphasizing the value of manipulation in disease, but in laying stress on cases which have previously been ignored or undiagnosed by the profession."

I wrote these words in 1910, and I can only add that from my increased experience I am more than ever satisfied that in manipulative therapy we have a valuable method of curing many cases otherwise incurable. I do not hesitate to plead for the admission of this new form of scientific bone-setting among the recognised methods of treatment practised by the medical profession.

I am, Sir, yours faithfully,
ALEXANDER BRYCE, M.D., D.P.H. Camb.
Birmingham, March 17th, 1930.

THE ENDOWMENT OF PATHOLOGICAL RESEARCH AT WESTMINSTER HOSPITAL.

To the Editor of THE LANCET.

SIR,—I write on behalf of my uncle Mr. A. J. H. Carlill, who in 1924 endowed the work of pathological laboratories at Westminster Hospital in order to commemorate the life of his father Dr. John Burford Carlill, to ask you to allow him to express to Miss K. Chevassut his congratulations on her research into the cause of disseminated sclerosis. If in 1924 we at Westminster Hospital had cause for congratulating him and ourselves that his munificent gift was made during his life, Miss Chevassut's work, apparently of far-reaching importance and done in the few years which have elapsed since 1924 and also during his life, must be a source of the greatest possible gratification to him. My uncle is on holiday in Australia.

A few points stand out on the clinical side. Miss Chevassut's discovery of the "specific" organism appears likely to enable us to diagnose the disease with certainty. Formerly a firm clinical diagnosis was by no means always easy, especially in early cases, and I may point out here that routine examination discloses for example abolition of epigastric and abdomina reflexes in a number of young people who claim n symptoms which are even suggestive of disseminate sclerosis and who appear never to have the disease Miss Chevassut's discovery helps us also in the diag nosis of those often very difficult cases of coexisting disseminated sclerosis and hysteria. Lastly, we are now able to recognise with precision "cure" as distinct from remission, although we shall not expect every abnormal physical sign to disappear in cases of "cure." In a recent case of my own in which the prominent signs were an alternating hemiparesis and also palsy of a sixth cranial nerve almost complete clinical recovery from an illness which had lasted for two and a half years occurred within six months of treatment, and the cerebro-spinal fluid which was bacteriologically affected prior to treatment became sterile within the same six months. The only treatment was a single course of vaccine administered intravenously.

---

[1] Brit. Med. Jour., Sept. 3rd, 1910.

Future clinical workers should bear in mind the very real necessity of making thecal punctures which are perfect, and therefore painless. Arsenical injections, our stand-by in the recent past, should not be given to patients who are to be investigated by Miss Chevassut's methods. Permit me please to end this letter with an expression of my own congratulations to Miss Chevassut and to her co-workers in the John Burford Carlill laboratories.

I am, Sir, yours faithfully,
HILDRED CARLILL, M.D. Camb.,
Physician and Lecturer on Nervous Diseases, Westminster
Hospital and Medical School; a Trustee of the
John Burford Carlill Pathology Fund.

ÆTIOLOGY OF ENCEPHALOMYELITIS FOLLOWING SMALL-POX.

To the Editor of THE LANCET.

SIR,—As Dr. Troup and Dr. Weston Hurst have raised the question of the ætiology of encephalomyelitis following small-pox (THE LANCET, March 18th, p. 566), might we be allowed to comment on their conclusions? In their article, Drs. Troup and Hurst describe in detail a case of encephalomyelitis following small-pox, and show that the pathological lesion is essentially similar to that of post-vaccinial encephalitis; this they assume as indicating the awakening of some mysterious latent infection in both conditions. It seem to us that the reverse is the case, and that their essential similarity is strongly in favour of the fact that both conditions are due to the virus of variola. They also draw attention to the encephalitis which has been described as a complication of measles.

Time and space will only allow us to mention a few of the facts which can be adduced to refute their contention, quite apart from the all-important fact that so far no virus other than that of the disease has been isolated from these cases of encephalomyelitis.

It is well recognised that very similar histological lesions may be produced in ordinary tissues by different ætiological agents, as, for instance, in the case of syphilis and tuberculosis. Then how much more likely in the brain, where the type of reaction is necessarily limited, are similar histological lesions likely to be produced by different viruses; although certain well-marked types of lesions can be differentiated. But the encephalitic conditions with which we are dealing are mainly found in the later stages of general exanthematous diseases (variola, vaccinia, measles, &c.), the viruses of which are likely to have very similar actions. In typhus fever, for example, cerebral involvement is so frequent as to be reckoned part of the disease, and no latent virus can be postulated, yet the histology of the lesion is comparable with that of post-vaccinal encephalitis. Again, on the development of nervous symptoms in syphilis, no matter at what stage, there is no suggestion that a latent virus is at work. Lastly, clinical experience has in general shown that it is unwise to assume without adequate evidence an infection by more than one organism, and in the instances mentioned the evidence is definitely against such an assumption.

No new reason or fact, therefore, has been brought forward by Drs. Troup and Hurst to indicate that the encephalitis in variola and in similar condition is not produced by the actual virus causing the exanthematous disease.

We are, Sir, yours faithfully,
JAMES McINTOSH,
R. W. SCARFF.

Hospital, W., March 18th, 1930.

PROTECTION AGAINST MEASLES.

To the Editor of THE LANCET.

SIR,—Allow me to endorse Dr. Hugh Barber's letter in your last issue. Several disastrous epidemics in preparatory schools have come under my notice and, in every case, the children are moved to the sick ward and it has been a frequent experience to see every window wide open, the children washed twice daily, and fed, more or less forcibly, with milky foods. It is under these conditions that broncho-pneumonia and mastoids are so frequent. On the other hand, where a child is at home, is put to bed at the onset of fever in a warm room, given plenty to drink and only the food it desires, the attacks are almost always mild and the temperature normal at the end of the fifth day. I believe most sincerely that the less exposure the better. There is no necessity whatever to stethoscope the child and, certainly in the winter-time, the window should only be open sufficiently to keep the room aired, and the temperature should be at least 62° F. with the child carefully protected from cold draughts.—I am, Sir, yours faithfully,
H. BECKETT-OVERY, M.D., F.R.C.S.
London, March 18th, 1930.

Obituary.

HENRY WILLIAM ARMIT, M.R.C.S. ENG.

We regret to announce the death in Sydney, New South Wales, of Dr. H. W. Armit, which occurred on March 12th, at the age of 59. He was until recently editor of the *Medical Journal of Australia.*

Henry William Armit was the son of the late William Armit, secretary to the Hudson Bay Company, and received his medical education at St. Bartholomew's Hospital, taking the London double qualification in 1894. He was for a time, after qualification, assistant medical officer at the Eastern Hospital of the Metropolitan Asylums Board, and was afterwards attached to the Lister Institute, but his knowledge of languages, mainly, led him to become a medical journalist. For this he was fitted, as he had, in addition to his practical knowledge, a broad outlook on professional questions. His services were largely used by the *British Medical Journal* as their representative at continental gatherings, and in this capacity he attended the International Congresses at Berlin in 1901 and 1907, at Paris in 1905, at Lisbon in 1906, at Cologne in 1908, and at Budapest in the following year. He was also for a time the London correspondent of the *Berliner Klinische Wochenschrift*, while his services were frequently used by THE LANCET as a topical correspondent. He was, as may be gathered, a good German scholar, and found time, in addition to his journalistic work, to translate two German books: one, the well-known book by Ehrlich and Lazarus, and the other a work by Professor von Schrötter, of Vienna, entitled the Hygiene of the Lung.

Just before the outbreak of war the *Medical Journal of Australia* came into existence, replacing two magazines, one of which was published in Sydney, and the other in Melbourne, and Armit went out, by invitation, to take the post of editor. The time was a difficult one for running what was practically a volition. He hoped the Minister as soon as the Bill reached the Statute Book would exercise to the full his powers to see that rules and regulations were passed which would really safeguard the people who were placed under control in the manner provided by this Bill.

The clause as amended was added to the Bill.

The Committee adjourned.

The Mental Treatment Bill was further considered by Standing Committee A of the House of Commons on Tuesday, March 18th. Mr. CECIL WILSON was in the chair.

Powers and Duties of Local Authorities.

On Clause 6 Mr. GREENWOOD (Minister of Health) moved an amendment in order to make Subsection (1) read as follows:—

> "It shall be the duty of every local authority to investigate the needs of their area and to take such steps as they consider necessary to provide and maintain suitable accommodation for the reception of temporary patients under the last foregoing section of this Act."

He said that he would have preferred the Bill to remain as it was, but he was very anxious to meet the wishes of the local authorities as far as possible, and to secure their goodwill, and therefore he had agreed to this amendment. But he had pointed out to the County Councils Association that under Section 104 of the Local Government Act it would be quite possible for the Minister to reduce the block grant to local authorities which failed to institute and maintain a reasonable standard of progress in relation to public health services. By a later section of the Local Government Act it was stated that this provision applied to lunacy and mental deficiency. The local authorities would be required to make their own investigation of their needs, and to take steps to put their own plans into operation. Whether the authorities would suffer financially depended on the circumstances. He had no intention or desire to bully local authorities; his powers would only be exercised in this matter when he could justify them to Parliament.

The amendment was agreed to.

Mr. GREENWOOD moved an amendment to the effect that a local authority should have power, subject to the approval of the Board of Control, to contract for the reception and treatment of temporary patients in any registered hospital, or any institution, hospital, or nursing home, approved by the Board of Control.

The amendment was agreed to.

Board of Control and Local Authorities.

Mr. GREENWOOD moved the first of a series of amendments which he said were designed to give greater freedom to local authorities from interference by the Board of Control, except in respect of research. It was desirable that the Board of Control should retain its powers in that regard in order to secure the maximum amount of coöperation, to avoid duplication, and to produce the best results. These amendments were of considerable importance, and had been framed after consultation with the County Councils Association in order to meet their views.

Lieut.-Colonel FREMANTLE said while he agreed that it was necessary to give the utmost possible liberty to the local authorities in this matter, which was consistent with the coöperative working of the whole machine, he was not altogether pleased with the removal of the approval of the Board of Control under the amendments before the Committee. If the Board worked sensibly, it was desirable that they should have supervising power over the whole of this machine. He therefore thought that the Bill as originally drafted was right, but as the County Councils Association has taken up this line it was expedient to meet their views. He hoped, however, that the county councils would enable the Board of Control to work the whole machine as they would have done if the Bill had remained unaltered. He was very glad that the Board of Control were to retain in their hands the matter of research. A great deal of money was being wasted under the heading of research in this country to-day, and it was necessary to be careful in order to prevent the word research being used as an excuse for spending money. It was necessary to see that research was coördinated and that overlapping was prevented.

Dr. MORRIS-JONES associated himself with the remarks of Colonel Fremantle. He could not understand the tremendous fear which existed in regard to the Board of Control. The Minister had been very conciliatory, and he was not quite sure that in time it would not be discovered that the right hon. gentleman had been too conciliatory in this matter. He would have thought that local authorities would have welcomed a certain measure of approval coming from an expert body like the Board of Control.

Sir DOUGLAS NEWTON congratulated the Minister on his courage in making this considerable alteration of the Bill to meet the reasonable representations of the County Councils Association. Local authorities in the past had been very irritated by the interference of the Board of Control in these matters, especially in view of the fact that the Exchequer did not find any of the cost. He was anxious to know whether the new freedom accorded to local authorities included questions relating to buildings used in connexion with mental treatment.

Mr. GREENWOOD said that no doubt local authorities would like to revise the whole of the system of central controls set up under the principal Act, but that could not be done under this Bill. The new freedom being accorded to the authorities applied to this section alone, and if the local authorities meant more than that they were trying under the guise of an apparently innocent series of amendments to make a fundamental change in lunacy administration laid down in the principal Act. The position in regard to buildings was unaltered by these amendments. The control of the central authority set out in Section 254 of the principal Act remained in operation. He would like to remind the Committee again that this Bill did not deal with the larger problems of lunacy administration provided for in the principal Act.

The amendments were agreed to.

Other Amendments.

Mr. KINLEY moved an amendment to limit the expenditure under Subsection (4) of Clause 6 to the proceeds of a halfpenny rate. He said that the local authorities to-day were heading towards bankruptcy. Year by year Parliament was throwing upon them increased financial burdens which their resources were not expanding to meet.

Mr. GREENWOOD said that while it was quite true that no one could say at present what the expenditure would amount to under this measure that was also true of most social legislation which had been passed. It was in any case very difficult to limit by Statute the expenditure of local authorities in the way proposed by this amendment.

The amendment was negatived.

Mr. GREENWOOD moved an amendment which he said was necessary in order to bring the new transferred institutions which the local authorities might use under the Local Government Act for the purpose of mental treatment under the same rules and regulations as applied to the other institutions which were already used for that purpose.

The amendment was agreed to.

Mr. GREENWOOD moved an amendment providing that the Asylums Officers' Superannuation Act, 1909, should have effect as if for references therein to mental hospitals there were substituted references to institutions maintained by local authorities.

The amendment was agreed to.

Clause 6 as amended was added to the Bill.

The Committee adjourned.

EYE TESTS FOR MOTOR DRIVERS.

The Road Traffic Bill was considered by Standing Committee C of the House of Commons on Tuesday, March 11th. Sir HUGH O'NEILL was in the chair.

Provisions as to Physical Fitness of Applicants for Licences.

On Clause 5 Dr. SALTER moved an amendment to Subsection (1) providing that an applicant for a licence should produce a certificate showing that he had satisfactorily passed an eyesight test as to visibility and colour. He said that he gathered that it was the intention of the Minister of Transport when this Bill became law that every applicant for a licence should make a declaration of a somewhat elaborate character as to whether he was suffering from certain physical disabilities. He also understood that the Ministry of Health had drawn up a form, and that the list of the said disabilities was quite lengthy. From his (Dr. Salter's) point of view, any such declaration was quite useless, especially in regard to conditions affecting the eyesight. There were large numbers of people suffering from grave visual defects who were quite unaware of any defect, and could quite honestly make a declaration that they were physically fit and capable of driving, and at the same time they might be extremely dangerous persons when in charge of a motor vehicle on the road. The only safeguard was to insist that everyone should produce an appropriate medical certificate in the prescribed form. During the past week he had had conversations with four or five of the most experienced and distinguished ophthalmic surgeons in London. They all told him that they had seen people suffering from grave eye trouble in the last year or two, and the first intimation that those people had that they had a visual defect was when they met with an accident while driving a car. Enormous numbers of drivers had got defective eyesight and no one knew for how many accidents they were responsible.

Four Classes of Visual Defectives.

There were at least four classes of persons suffering from visual defects who ought not to be permitted on the roads at all. The first was the class of people with extreme myopia. There had been a considerable number of dangerous driving cases where men had put up a plea that it was due to shortsightedness. In the Tiverton division last year a man put up such a plea and he was fined £5 and his licence was suspended for 12 months. But his eyesight would not be better after 12 months. In a letter to the *Times* the editor of the *Optician* pointed out that there was a growing practice, not only of having colour signals for the direction of road traffic, but also various forms of semaphore, and that the size of the letters forming the word "stop" on a revolving signal were visible only to drivers with a good standard of vision. At least one driver in 100 failed to see this signal. Again, there were thousands of cases where people had put forward the excuse that they were unable to read the particular sign exhibited for their guidance. The second class of person who ought not to be allowed to drive, at any rate after dusk, was the person who suffered from night blindness. There was a very large proportion of people, certainly not less than 5 per cent. of the population, who suffered from night blindness—that was to say, they either could not see at all in the dark, or their vision was extremely defective. There were people, on the other hand, whose vision was better in the dark than it was by day. There was an increasing proportion of accidents at night and after dark, to which the London and Home Counties Traffic Advisory Committee called the attention of the Minister in their recent report. In the report on street accidents in Greater London, March, 1927, it was pointed out that the percentage of persons killed by motor vehicles by day had gone down from 77·5 to 68·5, whereas the percentage killed at night had gone up from 22·4 to 31·5; those injured by day had gone down from 83·6 to 76·3, and those injured by night had gone up from 16·4 to 23·6. It was only right that persons should be duly certified as physically fit to drive at night. Another class of person was that suffering from various diseases of the eye itself, and the central nervous system, whose field of vision was obscured or completely blotted out at places.

It was an interesting fact that a great many of these people first sought medical advice for diseases of the central nervous system, like disseminated sclerosis and locomotor ataxia, because they had discovered the defect through having met with an accident. They ought not to be allowed to drive on the roads. There was a certain type of person who, with the passage of years, suffered from a steady diminution of the circumferential area of the field of vision. At least one Member of the House of Commons had told him that he was obliged to give up driving because he could only see straight in front of him. That was a matter which led to accidents and prevented a driver seeing cars coming out of side roads. There was a still more important visual defect which would grow in importance in coming years if the present system of regulating traffic by means of signals was extended.

Automatic Colour Signals.

It was clear that the Minister of Transport was encouraging all the great towns to establish automatic colour signals. There could be no dispute, however, that many thousands of people were totally colour blind. Swansey, in his authoritative work on diseases of the eye on page 10, said :—

> "A certain proportion of people, 3·5 per cent. of men and about 1 per cent. of women, are congenitally colour blind in greater or less degree."

These people could not possibly obey the signals. As a matter of fact people had been charged with overrunning the colour signals—he believed in Derby and other northern towns—who pleaded that they were colour blind. The railway companies discovered that at least 2·2 per cent. of men examined for the post of driver or fireman were practically colour blind. It was a remarkable fact that a man might pass a colour test one year and five years later it might be found that his colour vision was defective and he had to be displaced. In Germany a strict medical test was enforced. An official doctor had to be engaged at a fee fixed by the State, and within the last 12 months in Prussia a compulsory test for colour blindness had been included. If Parliament was desirous of protecting the public from accidents on the roads and of safeguarding human life it was essential that tests for sight should be imposed and a proper certificate submitted.

Lord ERSKINE submitted that the words of the amendment were really redundant. If a man was so extremely shortsighted that he could hardly see at all he imagined that that would be one of the disabilities included under the clause. Colour blindness was a very unfortunate thing, but he did not think that they could say that because a man happened to be colour blind he should be debarred from driving. If they were going to have this system of lights they must make some provision for those who were colour blind, because he understood that disability was increasing.

Major HILLS said he hoped that something could be done in the direction of the amendment.

A Standard of Shortsightedness.

Mr. HERBERT MORRISON (Minister of Transport) said he did not want to make the absolute bars to receiving a licence too numerous, because there was a whole field of diseases or disabilities where there was an element of doubt. But certainly he would regard extremely short sight as one of the disabilities which would be specified in the form, and would be an absolute bar to the grant of a driving licence.

Lord ERSKINE: Uncorrected by spectacles?

Mr. MORRISON said that even with spectacles, if a man were still definitely shortsighted, that would be an absolute bar to driving.

Dr. SALTER asked the Minister up to what point he put the limit? Was it 25 per cent. or 50 per cent. of the normal vision?

Mr. MORRISON said he could not get as far as that point at this stage, but the standard would be laid down in the form, and it would be for the applicant to satisfy himself that his sight reached that standard. But it was not proposed that applicants should produce any form of medical certificate. There were two ways in which the medical certificate could be dealt with. The applicant could go to his own medical adviser or ophthalmic surgeon—but with great respect to the profession there would not be complete reliance that medical certificates were always given in strict accordance with the facts when perhaps a man's employment might depend on the result of the certificate. The alternative method would be that there should be doctors in the public service who would be employed on this work. He was suspected, during the Second Reading of the Bill, of intending to appoint an army of officials, but he was afraid he would have to appoint such an army of officials if all that work was to be done. Therefore that scheme seemed to him to break down. It must be remembered that a man who made a false declaration was liable to very severe penalties—namely, £50, or six months' imprisonment or both. If a man knew that and also that he might be involved in an accident because of a defect which he did not declare he would be very careful about making false declarations in his application for a licence. In Subsection (4) of Clause 5 of the Bill it was provided that a licensing authority which suspected that a man was suffering from a disease or physical disability, either at the original granting of the licence or at any subsequent time, might revoke the licence. Therefore there was a running check all the time. If the purpose of this amendment was to be met there would have to be a medical examination on the granting of the first licence, and every year on its renewal. That would involve the appointment of an army of medical men and cause irritation and trouble to the drivers in having constantly to undergo these tests. As to the light signals, a man who was colour blind could at any rate in the daytime see the position of the light. The positions would be regular, and drivers would know whether it was the first, second, or third light. The same men would be able normally to read the word "stop," "go," or "caution"; and there was therefore a check there. Finally, the man who knew that he was defective in this regard and might get into difficulties would probably have someone with him who would be able to point out these things. He agreed that this was not a completely satisfactory assurance, but it was sufficient to warrant the Committee in not imposing conditions which would be vexatious and irritating to a large and eminently respectable section of the community who would resent these numerous tests. The clause as it stood was reasonable and went as far as they could go at the moment.

Mr. GEORGE OLIVER said he was authorised to say that the people employed in driving commercial and passenger vehicles viewed this amendment with grave apprehension. If the tests outlined that day were to be applied there was hardly 1 man in 100 who would escape.

The amendment was rejected by 44 votes to 4.

Driving Tests.

Mr. D. HALL CAINE moved that applicants for licences should be required to satisfy the licensing authorities of their competency to drive with reasonable skill, and of their knowledge of the rules of the road. He said this country had by far the largest proportion of accidents compared with any other, and it was practically the only country where there were no driving tests. The standard of driving in this country was bad.

Lieut.-Colonel HOWARD-BURY said that driving tests in other countries were in most cases an absolute farce. The dangerous drivers who took risks would be able to pass all the tests and the Royal Commission had pointed out that a very small percentage of accidents was caused by inexperienced drivers.

Mr. Morrison said the Ministry of Transport and the local authorities could appoint large numbers of officers to administer driving tests; but it was doubtful if Parliament would assent to the expenditure involved, and the question arose whether the results of the tests would be worth the money spent on them. The tendency would be for the tests to be perfunctory. The person who they wished to get at was the dangerous driver who would be able to pass all the tests with ease.

The amendment was rejected by 36 votes to 10 and Clause 5 was then agreed to.

MEDICAL OFFICERS FOR THE NAVY.

On Monday, March 17th, Mr. Alexander, First Lord of the Admiralty, in moving that the House of Commons go into Committee on the Navy Estimates, said that the Medical Director-General had reported that the health of the Fleet personnel had been very good for the past 12 months, and no serious epidemics had occurred. Some concern was felt, however, by his advisers in regard to the difficulty of obtaining an adequate supply of medical officers in spite of the very special efforts made during the past 12 months by the Medical Director-General. As the medical profession was not without some direct representation in the House of Commons, he hoped that they would be able to use some influence in the direction of assisting the Admiralty on this matter.

Welfare of the Sailor.

Very substantial provision was now made for the welfare of the men, which was a great factor in maintaining general health and efficiency. The pressure of preliminary naval negotiations and the Conference itself had prevented him (Mr. Alexander) from giving the amount of personal attention which he would like to this side of the Admiralty's activities, but the welfare work had been going on well, and in the conferences which were to meet shortly, opportunity would be given for new suggestions to be considered. He was much impressed in the course of a short visit to the Atlantic Fleet, during the autumn exercises, with the general fitness, keenness, and efficiency of the men in the Service, and it was not surprising that they were welcomed in countries all over the world.

The Vote for personnel was afterwards considered in Committee.

Major Ross said that it appeared that nearly all the stores were being reduced—victualling, clothing, and even medical.

Mr. Alexander pointed out that he had explained that he had to meet commitments this year made by his predecessor, a large proportion of which was in respect of additional stores.

Major Ross said that the Navy Estimates showed that there was a large decrease in stores. There were reductions in medical and surgical stores. The sum provided by the First Lord for the provision of medical stores and surgical appliances had been reduced by some £11,000, and he suggested that the First Lord was not keeping the stocks which had been supplied up to the standard. It seemed to him that the stores were being cut dangerously low.

Shortage of Medical Officers.

Dr. Vernon Davies said that the First Lord of the Admiralty, in his statement to the House, showed that he was rather perturbed at the lack of medical officers. He was reducing the personnel of the Navy by 2750, and he had said that he could not understand why the medical services, not only of the Navy but the Army, were not more popular. He (Dr. Davies) suggested that probably the terms were not quite good enough, and yet the terms were very good. The First Lord had visualised a time when boys from elementary and secondary schools would pass through the university and into the Services of the Crown. They were doing that now in the medical profession, and that was the difficulty that they were up against. If he might say so, without offence, medicine was becoming more of a trade and less of a profession. Many of these young men had no money; they had spent all their money on their education. They had become qualified and were out to do the best they could for themselves. They had several opportunities before them in civil life. A young doctor could set up in a national health insurance panel practice, and there were other openings, but if he went into the Navy, even on the short service system, though he could go out with a gratuity of £1000, he had to give three years or five years of his life. He had to go abroad. He dare not get married because the Admiralty would not give him a pension. On the other hand, those who did not go into the Service but stayed at home could earn as much money; they could get married and enjoy home life. They had before them specialised services, such as tuberculosis service, school medical services, and others in which they could work for six or seven hours a day on five days of the week, and earn from £600 to £900 a year. With that prospect on shore, why should a young doctor go to sea? He would be very silly to do so, unless he had a great love of the sea. The First Lord might make up his mind that the medical services of the Crown would have to be amalgamated. It was no use asking the heads of the separate medical services to agree to such a proposal, because they were not going to commit hara-kari.

Preferential Claim on Crown Appointment.

The Government would have to make up their minds that when they wanted medical men they were in competition with the great civil medical services of the country, both national and municipal. His (Dr. Davies's) suggestion, for what it was worth, was: Would it not be possible to give to men who had served in one or other of the Services for five years a preferential claim on all medical appointments under the Crown, or under the municipalities? It really was a question of choice between a man who had given five years of his life to the service of the country voluntarily and the man who had stayed at home. When the Government wanted a medical man for a post under the Ministry of Health, or any other Department, the man who had served his country for five years should have a preferential claim. By offering an inducement like that they would get these young men into the Service. Unless they had an efficient medical service they would not get a healthy Navy; if they did not get a healthy Navy they would have an inefficient Navy, and, as would be remembered, it was the medical men who won the war. There was never a war in all history where there was less sickness and disease, or where more people were cured after being disabled. It was the medical profession, absolutely, which won that war by keeping the men fit. It was no use having the ships unless the men were healthy and fit; and he hoped that the First Lord would not be discouraged at the lack of entries into the medical service, but would recognise that there were more tempting offers made outside, and that it was up to his Department to see if they could not make the Service more attractive to these men.

The Vote was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 12TH.

Institutional Accommodation for Mental Defectives.

Dr. Vernon Davies asked the Minister of Health the number of local authorities who had provided any accommodation for mental defectives, the number who had failed to do so, and the estimated number of mental defectives for whom no institutional accommodation was available.—Miss Susan Lawrence (Parliamentary Secretary to the Ministry of Health) replied: Twenty-nine out of 1924 local authorities (or combinations of authorities) have made some provision for the residential care of the mentally defective. As my right hon. friend stated in reply to a similar question on Dec. 19th, the present accommodation is inadequate; and if the figures estimated by the Departmental Committee on Mental Deficiency be accepted, the shortage of beds would probably be approximately not less than 20,000.

Repair of Hospital Ship "Maine."

Sir Robert Gower asked the First Lord of the Admiralty whether he would consider the desirability of placing the order for the construction of the contemplated new hospital ship with the Royal Naval Dockyard at Chatham.—Mr. Alexander replied: No new hospital ship for the navy is included in the present programme of new construction; but the existing hospital ship *Maine* is now undergoing large repair at Chatham dockyard.

Government and the Factories Bill.

Sir Kingsley Wood asked the Prime Minister whether he proposed to give facilities this session for the Factories Bill.—Mr. Snowden (the Chancellor of the Exchequer) replied: I regret that in the present state of public business I am unable to say when this Bill can be introduced.

Silicosis and Disablement.

Mr. Kelly asked the Home Secretary how many cases of disablement from silicosis were reported in 1929; the number partially disabled, with the number permanently disabled; and the number of fatal cases.—Mr. Clynes replied: The only complete figures I can give at present for 1929 are those of cases dealt with under the Compensation Schemes for silicosis in the refractories and sandstone industries. Under the Refractories Scheme there were 18 cases of partial and one case of total disablement, and ten fatal cases. Under the sandstone scheme (which came into force only on April 1st last) there were two cases of partial and seven cases of total disablement, and five fatal cases. The figures for the industries included under the other two schemes now in force are not yet available, but roughly 100 cases in these industries—about half of which were fatal—have come to the notice of the Department.

THURSDAY, MARCH 13TH.

Alleged Interruption of Antivivisection Meeting.

Mr. FREEMAN asked the Home Secretary whether he was aware that at a public meeting held in the Friends Hall, Euston-road, W.C., on Thursday, Feb. 27th, 1930, to protest against the use of poison gas in experiments on dogs, there was an organised attempt to interrupt the meeting by medical students in spite of the efforts of from 20 to 30 policemen and about 40 stewards; and whether he would take measures to see that such meetings were protected from disturbance.—Mr. CLYNES replied: No, Sir, my information is quite different. A number of police were available but their assistance was not called for or required, and I am informed that the stewards had no occasion to take action against interrupters.

Medicated Baths and Rheumatism.

Mr. LEE asked the Minister of Health whether he was prepared to make grants to enable urban district or county councils to provide medicated baths for the treatment of rheumatism and kindred complaints at such public baths or hospitals as might now be in existence, or to erect special baths for the purpose.—Mr. GREENWOOD replied: I have no funds at my disposal from which grants could be made for this purpose.

The Treatment of Rheumatism.

Mr. GRAHAM WHITE asked the Minister of Health whether in view of the suffering and loss of national efficiency due to the incidence of rheumatic diseases, he would set up a committee to consider the best means of extending facilities for treatment and making a comprehensive attack on this evil.—Mr. GREENWOOD replied: Until further experience has been gained of the treatment of rheumatism at the new clinic established by the British Red Cross Society and elsewhere, I think it would be premature to consider the appointment of a committee for the purpose referred to by the hon. Member. But I shall be prepared to give sympathetic consideration to any practicable proposals which may be submitted to me by local authorities for the provision of facilities for treatment.

Institutions for Mental Patients.

Mr. KINLEY asked the Minister of Health the number of establishments in which lunatics were treated and the number of patients therein, showing the positions of those under local authority and private ownership, respectively.—Mr. GREENWOOD replied: The table indicates the number of institutions in which persons of unsound mind (voluntary and certified) are received, and the number of patients (voluntary and certified) under care on Jan. 1st, 1930, in England and Wales:—

Number of Institutions	Type of institution.	Number of patients resident.
(1) .. 99	County and Borough Mental Hospitals	117,486
(2) .. 14	Registered Hospitals	2,493
(3) .. 54	Licensed Houses	2,964
(4) .. 1	Royal Naval Hospital	115
(5) .. 1	Military Hospital	37
(6) .. 1	Criminal Asylum	827

(1) Provided by local authorities.

(2) Supported wholly or partly by voluntary contributions, or by charitable gift or bequest or by applying excess of payments of some patients for or towards support, provision, or benefit of other patients.

(3) Institutions under private ownership.

(4), (5), (6) Provided by the Admiralty, War Office, and Home Office, respectively.

Beds in Wells Mental Hospital.

Mr. GOULD asked the Minister of Health the largest number of beds in any one room now in use in the Wells County Mental Hospital, Somerset.—Mr. GREENWOOD replied: There are 75 beds in one dormitory of a size which gives 600 cubic feet of space for each occupant.

Mr. GOULD: Does the right hon. gentleman regard the mass sleeping accommodation as conducive to the best interests of the patients?

Mr. GREENWOOD: Unfortunately it is the best accommodation that they have at the moment.

Mr. GOULD: Will the right hon. gentleman make representations to the Wells Mental Hospital asking them for an early change in the dreadful conditions of the sleeping accommodation?

Mr. GREENWOOD: I will consider that suggestion.

Medical Officers in Poor-law Institutions.

Sir NICHOLAS GRATTAN-DOYLE asked the Minister of Health whether he had received any protests respecting the terms of his recent order affecting the relations of the master and medical officers in poor-law institutions.—Mr. GREENWOOD replied: The order to which the hon. Member refers has not yet been made, but has been published as a draft. I have received a number of representations in regard to the draft order which will receive my careful consideration.

The Virus of Psittacosis.

Mr. GRAHAM WHITE asked the Minister of Health if he could confirm the reported discovery and isolation of the virus of psittacosis at a London hospital.—Mr. GREENWOOD replied: The results obtained at this hospital have not yet been confirmed, but a great deal of work with the object of elucidating this disease is in progress, and I am hopeful of valuable results being obtained.

Lunacy Observation Wards.

Mr. ROBERT RICHARDSON asked the Minister of Health what would be the position of the lunacy observation wards, which at present formed a part of the poor-law infirmaries, after the poor-law guardians had been abolished; and would they be annexed to asylums or to voluntary hospitals.—Mr. GREENWOOD replied: The position of the observation wards will depend mainly upon the decision of the local authority in regard to the purposes for which the infirmary will be used; but I would remind my hon. friend that a provision is contained in the Mental Treatment Bill now before the House which will facilitate the use of these wards for mental patients.

Children in Poor-law Institutions.

Mr. JOWETT asked the Minister of Health the number of children of school age in poor-law institutions, including cottage and other children's homes, on the most recent date for which the information was available.—Mr. GREENWOOD replied: The number of children between 3 and 16 years of age in England and Wales in receipt of relief in poor-law institutions, including cottage and other children's homes and other separate establishments for children on the night of Jan. 1st, 1929, was 38,476. The returns received in my department do not distinguish children of school age.

MONDAY, MARCH 17TH.

Price of Quinine in India.

Major GRAHAM POLE asked the Secretary of State for India whether his attention had been drawn to the statement of the director of the botanical survey of India, in his report for 1928–29, to the effect that the poor in India were unable to purchase quinine at the price at which it was being sold in India, and that charitable dispensaries had to turn malaria-stricken patients away empty or with inadequate doses; and whether, in view of this position, the Government of India were taking any steps to reconsider its policy in regard to the cultivation of cinchona in India and the manufacture and distribution of quinine.—Mr. WEDGWOOD BENN replied: I have not seen the report referred to, but am asking the Government of India for an up-to-date report on the position.

Safety of British Hospital at Nanning.

Sir KINGSLEY WOOD asked the Secretary of State for Foreign Affairs whether he would make inquiries concerning the safety of some 20 girls attached to the Bible Churchmen's Girls' Orphanage, near Lungchow, which was recently looted by Communists; whether he would ascertain, in view of the safety of the occupants of the British Bible Churchmen's Hospital at Nanning, what was the present position there; and whether there had yet been any invasion by Soviet forces in this district.—Mr. HENDERSON replied: I have already made inquiries, and from such information as I have been able to obtain it would seem that the girls in question, who are Chinese, have been released. There is a scarcity of news from Nanning where the hospital in question is situated, but according to the latest reports foreigners are not thought to be in danger there at present, though unsatisfactory conditions prevail in the province generally. There has been no invasion by Soviet forces. The nearest point in this district to Soviet territory is about 2000 miles from the Soviet frontier.

Protection of Civilians against Gas Attack.

Mr. DAY asked the Prime Minister whether any decision had been come to with reference to the problem of the protection of the civil population against gas attack; whether any scheme had been prepared for the protection of the civil population in these emergencies in future; and whether this scheme had been communicated to the local authorities.—Mr. MACDONALD replied: As I have said in answer to previous questions on this subject, in view of the ratification, last year, of the Geneva Gas Protocol of 1925 by most of the important European States, including this country, and also in view of the other international undertakings and agreements for the preservation of peace, I do not think the present time opportune to press on with plans dealing with gas attack. It is, I think, well known, and has been stated in the House on more than one occasion, that considerable preparatory work had been done by the Committee of Imperial Defence upon this problem prior to the ratification of the Protocol. This work will always be available should it be necessary, at any time, to reconsider our position.

Disease Germs in Telephone Mouthpieces.

Mr. REMER asked the Postmaster-General if his attention had been called to the danger, according to medical opinion, of disease caused by germs lodged in telephone mouthpieces; and if his officers were considering any device to overcome this danger.—Mr. VIANT (Assistant Postmaster-General) replied: The view of the Post Office—based on competent medical opinion—is that the danger of infection from the use of telephones is negligible, although it is recognised that comfort and the general amenities demand that telephones should be kept reasonably clean. This is usually effected by subscribers themselves. So far as public call offices are concerned, it is the practice to disinfect the mouthpieces and earpieces at regular intervals, the frequency depending on the use made of the call office.

TUESDAY, MARCH 18TH.

Insanitary Conditions in Post Office Store.

Mr. WILLIAM BROWN asked the Postmaster-General whether he was aware of the outbreak of boils and carbuncles among the staff of the mechanical transport section of the Post Office stores housed in the old workhouse in Endell-street; whether he was aware that the accommodation in this building was infested with mice, which were themselves affected with skin diseases; whether he was aware that in the same building there was a bacteriological laboratory; and whether he would either remove his staff from the building or take steps to remove the vermin and the bacteria.—Mr. LEES-SMITH replied: This matter has been engaging my attention. It is the case that some members of the staff referred to have suffered from boils and carbuncles, A medical inspection has been made, and I am advised that there is no connexion between this outbreak and the proximity of a bacteriological laboratory or the presence of mice in the building. In view of the possibility that infection may have been spread by contact, disinfectant is now being used; and I am taking up the question of improving the sanitary arrangements. Urgent measures are being taken to exterminate the mice.

HOSPITAL COSTS.—Last year at Addenbrooke's Hospital, Cambridge, the average cost per week of each in-patient (3836) was £2 15*s.* 9½*d.*, an increase of 3*s.* 4½*d.* The average cost of each out-patient (12,104) was 6*s.* 9¾*d.*, an increase of 4¼*d.* At the Hampshire County Hospital, Winchester, the daily cost of each out-patient was 8*s.* 10*d.*, an increase of 5*d.* The cost of each out-patient, which had been estimated at 5*s.*, is now found by accountants to be 7*s.* 3*d.*—At the Bucks County Mental Hospital, Stone, the rate for the maintenance of patients from contributing unions was 19*s.* 10*d.* per head per week in the first half of last year and 19*s.* 3*d.* in the second half.—The cost per bed per week at Skegness Cottage Hospital (208 in-patients) was £1 19*s.* 0½*d.*—The weekly cost of an in-patient at Lymington Cottage Hospital (486 patients) was £2 3*s.* 2*d.*; at Horsham Cottage Hospital (482 patients) it was £3 8*s.* 10*d.*—At the Minehead and West Somerset Hospital last year the average weekly cost of each in-patient (812) was £2 18*s.* 10*d.* At the Pembroke County War Memorial Hospital the cost (645) was £2 8*s.* 5*d.* The cost of an in-patient at the Staffordshire General Infirmary, Stafford (1540 patients, average stay 15½ days), was £6 5*s.* 6*d.*, "less an estimated amount for out-patients." The Melton and District (Lincs) War Memorial Hospital spent £6 5*s.* per in-patient (599), a reduction of 18*s.* 1*d.*, X ray expenditure excluded. At Stroud General Hospital 789 in-patients cost £2 16*s.* 2*d.* per head per week.

Medical News.

UNIVERSITY OF CAMBRIDGE.—On March 14th the following degrees were conferred:—

M.B. and B.Chir.—R. M. Windeyer* and T. N. Parish.

* By proxy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Council was held on March 17th, with Lord Moynihan, the President, in the chair.

Licences in Dental Surgery were granted to the following candidates, who were successful in the recent examination:—

C. G. Baker, John Barnes, David Bengis, V. S. A. Biggs, John Carter, Q. A. Davies, A. M. Garman, A. T. Gibb, A. J. D. Gibbings, D. D. C. Hamilton, William Headridge, H. R. Heald, H. R. Heathcote, J. A. C. Hunter, C. E. W. Kurtz, F. G. Lilley, W. O. Littler, A. C. R. McLeod, Mary S. MacWilliam, H. C. Norman, G. B. Palmer, J. P. Price, F. I. Robertson, J. D. Sellers, H. M. Selmann, G. B. Shaw, F. A. Sickelmore, J. A. Singer, K. P. Smith, M. L. Smith, J. L. Thornton, J. H. White, R. E. Wiles, *and* W. R. J. Wood.

Diplomas in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Physicians, to 16 candidates.

Mr. C. H. Faggo was appointed the representative of the College to serve on a subcommittee of the People's League of Health to consider the subject of the Cause and Eradication of Bovine Tuberculosis.

Mr. Ernest W. Hey Groves was asked to represent the College at the annual meeting of the *Czecho-Slovakian* Orthopædic Society.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Feb. 26th an interim grant of £75 was made out of the Thomas Smythe Hughes Medical Research Fund to Miss Kathleen Chevassut for continuation of the research on disseminated sclerosis which she described in THE LANCET of last week.

Applications are invited for grants from this and from the Beaverbrook Medical Research Fund, and from the Dixon Fund for assisting scientific investigation. Particulars are obtainable from the Academic Registrar.

Regulations for the Academic Diploma in clinical pathology have been approved and may be had from the Academic Registrar.

UNIVERSITY OF LIVERPOOL.—On June 5th the honorary degree of D.Sc. will be conferred on Mr. George Barger, F.R.S., professor of chemistry in relation to medicine in the University of Edinburgh.

UNIVERSITY OF EDINBURGH.—The honorary degree of LL.D. is to be conferred on Sir Thomas Barlow, F.R.S., consulting physician to University College Hospital; Sir Otto Beit, founder of the Beit memorial fellowships for medical research; Sir William Hardy, F.R.S., Director of Food Investigation in the Department of Scientific and Industrial Research; Sir David Wallace, consulting surgeon to the Edinburgh Royal Infirmary; and Prof. Karel Wenckebach, of Vienna.

CAMBRIDGE GRADUATES' MEDICAL CLUB.—The annual dinner of this club will be held at the May Fair Hotel, London, W., on March 27th at 7.30 for 7.45 P.M., with Dr. H. Morley Fletcher in the chair. The hon. secretaries are Mr. Reginald M. Vick, 113, Harley-street, W.1, and Dr. F. G. Chandler.

ROYAL NAVY MEDICAL CLUB.—The annual dinner will take place at the Trocadero Restaurant, Piccadilly-circus, London, on Thursday, April 24th, at 7.30 P.M. for 8 P.M. Members who wish to be present are asked to inform the hon. secretary of the Club, Queen Anne's Chambers, Tothill-street, S.W.1., *not later than seven clear days before* that date.

SOCIETY FOR THE STUDY OF INEBRIETY.—The annual meeting of this Society will be held at 11, Chandos-street, Cavendish-square, London, W., at 4 P.M., on Tuesday, April 8th. Dr. Percy C. Barham will open a discussion on the Difficulties of the Institutional Treatment of Alcoholism and Drug Addictions.

ENLARGEMENT OF RUGBY HOSPITAL.—It is proposed to spend between £20,000 and £25,000 upon additions and improvements to St. Cross Hospital, Rugby. A pavilion for treating tuberculous cases is to be substituted for the existing wooden hut, better accommodation is to be provided for nurses. and it is expected that £500 a year will be saved by a modern system of warming. The hospital's income last year exceeded £19,000; before the contributors' scheme was adopted it only slightly exceeded £12,000. Over £1000 was saved on the year's working.

Christie Hospital, Manchester.—An anonymous gift of £2000 has been received by the treasurer of the Christie Hospital (Cancer Pavilion and Home).

The "Hope Journal."—Under the description of "the official journal of the Hope Hospital," Pendleton, the first number of this magazine has just been issued.

International League for Campaign against Trachoma.—This league, which was founded at the Thirteenth International Ophthalmological Congress, will hold its next meeting at Geneva on July 28th. The president is Prof. Emile de Grósz, and the hon. secretary Dr. F. Wibaut, whose address is Budapest VIII., Mária-utca 39.

Course on Surgical Tuberculosis.—Under the direction of Dr. Etienne Sorrel, a course on the treatment of surgical tuberculosis will be held at the Hôpital Maritime de Berck-sur-Mer, Pas-de-Calais, France, from April 14th to 19th. Particulars may be had from Dr. Delahaye at the hospital.

Extension of West Middlesex Hospital.—Sir John Ferguson, M.P., has laid the foundation-stone of a new maternity block in the grounds of this poor-law institution. The building will include five wards of four beds each, one of five beds, and six single bed wards, and accommodation for midwifery pupils.

York County Hospital.—The Military Tattoo of the Northern Command last year produced £1400 for this hospital. So many main roads converge upon York that the hospital receives a considerable number of road accidents cases. Last year it treated 141 such cases at a cost of £1260, towards which £413 was received.

The King at the London Hospital.—On Tuesday last week the King and Queen paid a private visit to this hospital so as to see it at work in normal conditions. Their Majesties visited five wards, including a children's ward, and inspected two new covered ways provided by Sir William Paulin and his daughter to avoid the necessity of the nurses crossing the garden or passing through the wards on their way to the nurses' home. In the radium laboratory they watched the making of radon.

Instruction on Birth Control.—A conference on the giving of information on birth control by public health authorities will be held at the Central Hall, Westminster, on Friday, April 4th. It is stated that 60 local authorities have asked the Ministry of Health to allow them to provide facilities for giving such information. The conference is being organised by a group of societies and tickets may be had from the secretary, 9, Parliament Mansions, London, S.W. 1. Among the speakers will be Mr. Harold Chapple, senior obstetric surgeon to Guy's Hospital, and Dr. Maitland Radford, medical officer of health for Shoreditch.

Oxford Ophthalmological Congress.—This Congress will meet at Keble College, Oxford, on Wednesday, July 9th, and will go on till the 12th. Dr. H. M. Traquair, Sir Farquhar Buzzard, and Prof. J. A. Gunn will open a discussion on Toxic Amblyopia; Sir Oliver Lodge, F.R.S., will give an address on Modern Theories on the Nature of Light; Prof. Artur Schüller, of Vienna, will speak on Recent Developments in Radiology associated with Ophthalmology, and Prof. Jules Gonin, of Lausanne, on Detachment of the Retina and its Treatment; and the Doyne Memorial Lecture will be given by Dr. Harry Friedenwald, of Baltimore, on Pathological Changes in the Retinal Blood-vessels and their Significance. The hon. secretary of the Congress is Mr. C. G. Russ Wood, 12, St. John's-hill, Shrewsbury.

Scholarships and Grants for Scientific Research.—The Council of the British Medical Association is prepared to receive applications for an Ernest Hart Memorial Scholarship, of £200, and three research scholarships, each of £150 per annum. These are given to candidates whom the Science Committee of the Association recommends for research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Each is tenable for one year from Oct. 1st, and reappointment is possible for not more than two additional terms. Scholars may hold junior appointments at a University, medical school, or hospital, provided the duties of these appointments do not interfere with their work as scholars. The Council also invites applications for Grants for the assistance of research into the causation, treatment, or prevention of disease. Preference will be given, other things being equal, to members of the medical profession and to applicants who propose to study problems directly related to practical medicine. Applications for Scholarships and Grants must be made not later than May 21th, on a form obtainable from the Medical Secretary of the Association, B.M.A. House, Tavistock-square, London, W.C.1.

Plymouth Hospitals.—The amalgamation has been proposed of the South Devon and East Cornwall, the Central, and the Royal Albert Hospitals. The last-named is at Devonport.

Manchester Northern Hospital. — At the seventy-fourth annual meeting it was reported that £81,020 had been received towards the £150,000 needed for the new hospital, for which the new site is being prepared. The new hospital will be a general one, and not one confined to women and children.

St. Andrew's Hospital, Dollis Hill.—Last November the number of beds was increased from 52 to 74, and new wards and a nurses' home are now being erected at a cost of £30,000. The hospital, which last year received 1218 in-patients, is under the care of Sisters of Mercy, and is intended chiefly for members of the professional and middle-classes of any nationality and creed.

National Gardens Scheme.—The movement for throwing open famous gardens for the benefit of the Institute for District Nursing and other nursing institutions has again been conspicuously successful. Last year it produced £7705, an increase of nearly £1,000 upon the amount obtained in 1928.

Three Generations of Hospital Service.—Dr. F. R. Mallett, President of the Bolton Infirmary, has been entertained at a complimentary dinner by the committee and honorary medical staff of the institution, in recognition of the services of his family and himself. Dr. Mallett's grandfather became connected with the hospital 113 years ago, and his own service extends over 35 years.

Camden-road Sunlight Clinic.—Sir William Hale-White, president of the medical advisory committee of the new Institute of Ray Therapy at 152–154, Camden-road, described the objects of the clinic at the opening ceremony on March 13th. The clinic has its origin[1] in the generous gift of Mr. G. F. Kimber, who subscribed £10,000 for building and equipment. Patients must bring a certificate from their family doctors, on which an estimate of their financial standing will be noted; they will be charged, according to their means, sums ranging from 1*s.* to 5*s.* for a treatment, and in necessitous cases treatment will be free. As the Institute is primarily for the benefit of poor persons, patients with private means will not be accepted. The three objects of the Institute are treatment, training, and research; cases were under treatment, even before completion of building operations, and over 200 patients have been treated since Jan. 9th. The London County Council school service and care committees are arranging for the treatment of groups of children, and a central room offers accommodation for group treatment on a large scale. In all, there are 18 lamps of the most recent pattern, and an X ray apparatus in addition; the upper floor of the building is divided into cubicles for special forms of treatment; two of these are devoted to the treatment of rheumatism, one to skin diseases, one to conditions of the nose and throat, one to tuberculosis, one to asthma, one to eye diseases, and two to gynæcological conditions. Much of the arduous work of preparation has been performed by Dr. William Beaumont and his wife, who have shown untiring energy since the inception of the scheme.—The Lord Mayor, Sir William Waterlow, said he understood that one of the purposes of the clinic was to stabilise the uses of ray therapy and to estimate its capacity for good. This would be the concern of the medical staff and the voluntary advisory committee. For his part he liked to think of clinics of this type as the poor man's Riviera. The work would not only include treatment and cure of the sick but reinvigoration of those deprived of sufficient sunlight—that prevention of disease which was better than cure. He declared the clinic open.—Mr. Kimber, in proposing a vote of thanks to the Lord Mayor, said the clinic had been born of a remark made by the hon. medical director two years before; speaking of ray therapy he had said: "If only we had the money there's no telling what we could do." The clinic owed much to the generous help of many friends, in service, goods, and money; the Hearts of Oak Benefit Society had made a grant towards the upkeep of the first 18 months.—A tour of the building was then made by the guests, and patients were observed receiving treatment in the cubicles. The water-cooled tungsten lamp for the treatment of asthma serves a double purpose, since its fumes are in themselves regarded as beneficial to the condition. The lamp for the treatment of eye diseases can be focused so that only a small portion of the lid or cornea need be under treatment at a time without danger to the rest of the eye. Other new designs of apparatus were demonstrated, including an infra-red lamp.

---

[1] See THE LANCET, Feb. 15th, p. 367.

NORTH ORMESBY HOSPITAL.—It is proposed to enlarge this Middlesbrough hospital at a cost of £30,000. It has already been twice extended since the war. It is claimed to have been the first English cottage hospital, but it was not founded until 1857. Warwick College hospital goes back to 1823, that at Frodingham, Lincolnshire, to 1844, and that at Ripon to 1850.

INFECTIOUS DISEASES HOSPITALS IN THE WEST RIDING.—Basing their views upon a report from the county medical officer, the public health committee of the West Riding county council recommend that the urban and rural districts should be grouped into a number of hospital areas, with ten groups for general infectious diseases and seven for small-pox. It is estimated that the cost will be £330,000. It is further recommended that the county council should contribute towards the cost of erecting new and enlarging existing hospitals.

BRISTOL GENERAL HOSPITAL.—Although there was last year an increase of income under nearly every heading, the excess of ordinary expenditure over ordinary income was £10,544. The adverse balance in 1928 was £12,197, and in 1927 £13,465, a total of more than £36,000 in three years. Most of the legacies received last year had to be used to meet the deficit. New male and children's wards and a new operating theatre are about to be built at a cost of £17,000.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—At the annual meeting last week it was stated that during the past year more beds had been opened and new departments installed. The increase of work in a building more than double the size of the old hospital increased the expenses by £13,000, which has, however, been more than met. The Guild of Gratitude has been "heartily received" by the patients, and now has more than 15,000 members, who have collected over £3000 in pence and shillings.

PUBLIC ASSISTANCE ARRANGEMENTS IN KENT.—Dr. Alfred Greenwood, the county medical officer, and Mr. John Moss, the county public assistance officer for Kent, have made a survey of the poor-law institutions in the county, and have prepared a joint report suggesting some measure of classification now or later. They observe that if a few institutions are developed on hospital lines there should be available in many parts of the county a specialised institution which should provide the skilled treatment required. To assist classification it might be found possible to appropriate suitable poor-law institutions, or portions of them, for the accommodation of groups of mental defectives who have hitherto been scattered about the county. Where in a particular area there are two or three institutions it should be possible to develop one of them on hospital lines. Classification by institution, it is pointed out, involves the necessity of an effective ambulance service, so that the sick can be transported rapidly to the place where especially skilled nursing is available.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, March 24th.—8 P.M., ODONTOLOGY. Paper: Sir William Willcox: Dental Sepsis—a Retrospect. Casual Communication: Mr. F. Coleman: Buried Mandibular Teeth with Crowns in Occlusion.

TUESDAY.—5 P.M., MEDICINE. Discussion on Syphilitic Aortitis. Opener: Prof. Erich Leschke (Berlin). Followed by Dr. J. Parkinson, Dr. J. Cowan, and Dr. T. F. Cotton. Other speakers will also take part.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Papers: Dr. P. J. Cammidge: The Hereditary Transmission of Hypoglycæmia in Mice. Mr. S. R. Douglas: The Preparation of Tuberculin. Mr. F. C. Minett: The Clinical Forms and Bacteriology of Bovine Mastitis. Dr. G. Scott Williamson: Prophylaxis against Goitre in Fish Hatcheries.

THURSDAY.—8.30 P.M., UROLOGY. Clinico-Pathological Evening.

FRIDAY.—DISEASE IN CHILDREN. Clinical Meeting at King's College Hospital, Denmark Hill, S.E. 4.15 P.M., Tea will be served. 4.30 P.M., Cases will be shown. 5 P.M., Discussion on Cases. 8 P.M., EPIDEMIOLOGY. Paper: Dr. William Fletcher: Typhus-like Diseases of Unknown Ætiology.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 24th.—8.30 P.M., Discussion on Coliform Infections of the Genito-Urinary Tract, to be introduced by Sir Thomas Horder and Mr. Kenneth Walker.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, March 28th.—8.30 P.M., Papers will be read by Dr. D. Kathleen Brown and Dr. B. B. Sharp on Vulvo-vaginitis. A Discussion will follow.

HUNTERIAN SOCIETY.

MONDAY, March 24th.—7.30 P.M., the Third Dinner Meeting (at Simpson's Restaurant, 2 and 3, Bird-in-hand Court, 77, Poultry, Cheapside). 8.30 P.M., Discussion on Athletics in Schools, to be opened by Dr. L. R. Lempriere, Dr. A. I. Simey, Dr. Helen Boyle, Mr. H. M. Abrahams, Dr. Adolphe Abrahams, and Group-Captain Martin Flack, R.A.F.

ROYAL INSTITUTION, 21, Albemarle-street, W.

TUESDAY, March 25th.—5.15 P.M., Dr. Charles Singer: Inductive Philosophy and Some of Its Instruments.

THURSDAY.—5.15 P.M., Mr. J. B. S. Haldane: Some Problems of Genetics.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 25th.—5 P.M., Dr. Carey F. Coombs: Syphilis of the Heart and Great Vessels. (Second Lumleian Lecture.)

THURSDAY.—5 P.M., Dr. Carey F. Coombs: (Last Lumleian Lecture).

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, March 26th.—4 P.M., Mr. Harold D. Gillies: Plastic Surgery. (Lantern lecture.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

THURSDAY, March 27th.—9 P.M., Dr. Clayton: Fibrositis and Its Treatment.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 24th, to SATURDAY, March 29th.—MEDICAL SOCIETY Lecture Room, 11, Chandos-street, Cavendish-square, W. Tues., 4 P.M., Lecture by Mr. A. Tudor Edwards: Modern Surgical Developments in Chest Disease. No fee.—VICTORIA HOSPITAL FOR CHILDREN, Tite-street, S.W. Thurs. at 2 P.M., Demonstration by Mr. Max Page. No fee.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E.—Special Post-graduate Course in Medicine, Surgery, and Gynæcology. Operations and Lecture-demonstrations in the Wards and Out-patient Departments.—WEST END HOSPITAL FOR NERVOUS DISEASE, 73, Welbeck-street, W. Special post-graduate course of lectures and clinical demonstrations. Daily at 5 P.M.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Post-graduate course in Venereal Disease. Clinical instruction daily in the afternoons and evenings.—Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, March 24th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose, and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases. Clinics. Operations.

NATIONAL HOSPITAL POST-GRADUATE COURSE, Queen-square, W.C.

MONDAY, March 24th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Adie: Forms of Muscular Atrophy.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: Acute and Subacute Myelitis.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Neuralgia in the Distribution of the Cranial Nerves.

FRIDAY.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Disseminated Sclerosis.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.

TUESDAY, March 25th.—5 P.M., Dr. J. A. Willett: The Importance of Antenatal Care.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.

FRIDAY, March 28th.—4 P.M., Mr. Harold Kisch: Nasal Obstruction.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, March 26th (at St. John's Hospital, 49, Leicester-square, W.C.)—4.15 P.M., Clinical Cases. 5 P.M., Dr. J. O'Donovan: The Significance of Pattern Reaction in Dermatology.

ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square, W.C.

WEDNESDAY, March 26th.—6 P.M., Mr. J. G. Turner: Extraction.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, March 25th.—5 P.M., Dr. H. MacCormac: Malignant Growths of the Skin.

THURSDAY.—5 P.M., Dr. W. N. Goldsmith: Benign Growths of the Skin.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, March 25th.—4.15 P.M., Mr. A. H. Burgess: Spinocain Spinal Anæsthesia.

Friday.—4.15 P.M., Mr. H. H. Rayner: Demonstration of Surgical Cases.

ANCOATS HOSPITAL POST-GRADUATE COURSE, Mill-street, Manchester.

Thursday, March 27th.—4.15 P.M., Dr. N. Kletz: Affections of the Kidneys with Special Reference to Nephritis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

Friday, March 28th.—3.30 P.M. (at the Royal Infirmary), Mr. J. H. Cobb: Nasal Sinusitis.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, March 26th.—4.15 P.M. (Royal Infirmary), Dr. J. F. Smith: Skin Cases.

Appointments.

Badenoch, A., M.B., Ch.B.Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for East Linton (East Lothian).

Franks, C., M.D. Brux., L.S.A., D.P.H., Medical Officer of Health, Durham County, and **McIntyre, J.**, M.D., Ch.B. Edin., D.P.H., Deputy Medical Officer of Health.

Kiep, W. H., M.B., Ch.B. Glasg., to be a Specialist Medical Referee under the Workmen's Compensation Act, to take Ophthalmic cases arising in the Districts of the Bradford, Keighley, Skipton and Settle, Halifax and Huddersfield County Courts.

McKeggie, J. W., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health, West Hartlepool.

M'Polin, M.D., N.U.I., D.P.H., Medical Officer for Limerick County.

Sewell, D. Lindley, M.B., B.S. Lond., M.R.C.S., Honorary Surgeon-Laryngologist to the Manchester Radium Institute.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. At rate of £140.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £175.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.S. Also Asst. H.P. Each at rate of £100.

Bengal, Burdwar District, Asansol Mining Settlement.—Chief Sanitary Officer. Rs.1000 monthly.

Blackburn and East Lancashire Royal Infirmary.—4th H.S. £130.

Bolton Infirmary and Dispensary.—H.S. At rate of £150.

Bootle Borough Hospital, Derby-road.—Jun. H.S. At rate of £150.

Cardiff Royal Infirmary.—H.S. to Ophthalmic Dept. At rate of £75.

Charing Cross Hospital, W.C.—Asst. Physician.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Colonial Medical Services.—Medical Officers.

Connaught Hospital, Orford-road, E.—Sen. Res. H.S. At rate of £150. Also Jun. Res. H.S. At rate of £100.

Dartford, Kent, Darenth Training Colony.—Med. Supt. £1000.

Denbigh, North Wales Sanatorium, Llangwyfan.—Third Asst. Res. M.O. £250.

Derby, Bretby Hall Orthopædic Hospital, nr. Burton-on-Trent.—Asst. M.O. At rate of £150.

Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.

Durham County Council.—Venereal Diseases M.O. £750.

East London Hospital for Women and Children, Shadwell, E.—Cas. O. At rate of £125.

Edinburgh Hospital for Crippled Children.—Surgeon. £1000.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £150.

Folkestone, Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £125 and £100 respectively.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Radiologist.

Hackney Hospital, High-street, Homerton, E.—Asst. M.O. £350.

Hertford County Hospital.—Res. Surg. O. At rate of £250.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. Also H.P. At rate of £150 and £100 respectively.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. M.O. for County Branch Hospital, Tadworth, Surrey. At rate of £250.

Hull Royal Infirmary.—H.S. Cas. H.S. At rate of £150 and £130 respectively. Hon. Surgeon. Also Hon. Asst. Surgeon.

Inverness, Northern Infirmary.—H.P. and Jun. H.S. £100.

Ipswich, East Suffolk and Ipswich Hospital.—Two H.S.'s. Each £120.

Jerusalem, St. John Ophthalmic Hospital.—Registrar.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Liverpool, David Lewis Northern Hospital.—Res. M.O. £100.

London Homœopathic Hospital, Great Ormond-street, and Queen-square, W.C.—Res. M.O. £100.

London Hospital, E.—Asst. Radiologist.

London Lock Hospital, 91, Dean-street, W.—1st and 2nd H.S.'s. Each at rate of £200. Also Surg. Reg. £100.

London Lock Hospital, 283, Harrow-road, W.—Surg. Reg. £100.

London Temperance Hospital, Hampstead-road, N.—Res. M.O. Also H.P. At rate of £175 and £100 respectively.

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Hon. Asst. Surgeon.

Manchester, Victoria Memorial Jewish Hospital, Cheetham.—Hon. Radiologist.

Metropolitan Hospital, Kingsland-road, E.—Physician to Dept. for Diseases of Skin.

Middleton-in-Wharfedale Sanatorium, nr. Ilkley.—Jun. Res. M.O. £250.

Newcastle-upon-Tyne, City Mental Hospital, Gosforth.—2nd Asst. M.O. £400.

Northern Rhodesia, Roan Antelope Copper Mines, Ltd.—2nd M.O. £900–£1000.

Norwich, Norfolk and Norwich Hospital.—H.S. to Special Depts. Also Cas.O. and H.S. Each £120.

Nottingham General Hospital.—2nd Cas. O. At rate of £150.

Oswestry, Shropshire Orthopædic Hospital, &c.—Two H.S.'s. Each at rate of £200.

Paddington Green Children's Hospital, London, W.—H.P. and H.S. Each at rate of £150

Prince of Wales's General Hospital, Tottenham, N.—Hon. Phys. Also Sen. H.P., Sen. H.S., and Special H.S. Each at rate of £120. Also Jun. H.P., and Two Jun. H.S.'s. Each at rate of £90.

Rampton State Institution for Mental Defectives, near Retford, Notts.—4th M.O. £547 10s.

Reading, Royal Berkshire Hospital, Langley Hill, Calcot.—H.S. At rate of £160.

Royal Chest Hospital, City-road, E.C.—Res. M.O. Also H.P. At rate of £150 and £100 respectively.

Royal Northern Hospital, Holloway-road, N.—Pathologist. £750. Also Asst. Pathologist. £500.

St. Andrew's Hospital, Dollis Hill, N.W.—Sen. and Jun. R.M.O.'s.

St. Mary's Hospital, W.—Obstetric Regstrar. £50.

St. Mary's Hospital for Women and Children, Plaistow, E.—Asst. Res. M.O. At rate of £120. Also Clin. Asst. for Medical Out-patients Dept.

Salford Royal Hospital.—H.S. At rate of £125.

Shanghai Municipal Council, P.H. Dept.—Asst. Pathologist. 650 Taels per mensem.

Sheffield, Children's Hospital, Western Bank.—3rd Res. M.O. £100.

Sheffield Royal Hospital.—Ophth. H.S. Also Res. Anæsthetist. Each at rate of £80.

Sheffield Royal Infirmary.—Ophthalmic H.S. At rate of £80.

Southampton, Royal South Hants and Southampton Hospital.—Cas. O. At rate of £130 to £160.

Stockport County Borough, Stepping Hill Hospital.—Res. Asst. Med. Supt. &c. £350.

Stockport Infirmary.—Res. Surg. O. £250.

Surrey County Council.—Asst. M.O. £600.

Tiverton Hospital, Devonshire.—H.S. At rate of £100.

Watford, Herts, Peace Memorial Hospital.—2nd Res. M.O. At rate of £150.

West Bromwich and District General Hospital.—Cas. H.S. At rate of £200.

Westminster Hospital, Broad Sanctuary, S.W.—Hon. Asst. Administrator of Anæsthetics.

Woolwich and District War Memorial Hospital, Shooters-hill.—H.P. and H.S. Each at rate of £125.

Willesden General Hospital, N.W.—Clin. Assts. to Surgical Out-patients' Dept.

Winchester, Royal Hampshire County Hospital.—Hon. Ophth. S.

Births, Marriages, and Deaths.

BIRTHS.

Alden.—On March 13th, at Woodstock-road, Oxford, the wife of Dr. J. W. Alden, of a son.

Balfour.—On March 15th, at Downholm, Ringmer, Sussex, the wife of Ivor H. C. Balfour, M.R.C.S., of a daughter.

Gibson.—On March 11th, at Amalfi, Torquay, the wife of Paul C. Gibson, M.D., of a daughter.

Molesworth.—On March 13th, at Cleveland House, Brixham, Devon, the wife of Dr. Eric M. Molesworth, of a son.

Potts.—On March 16th, at The Gables, Bracknell, the wife of Dr. C. Lawrence Potts, of a son.

Scott.—On March 14th, at Abbotsford, Capel-road, East Barnet, the wife of C. Mervyn Scott, M.R.C.S., L.R.C.P., of a daughter.

Solomons.—On March 16th, at Meadway, Hampstead Garden Suburb, N.W., the wife of Dr. Barnet Solomons, of a son.

MARRIAGES.

Ainsworth—McKinley.—On March 4th, at West Kirby Presbyterian Church, Richard Murray Ainsworth, M.B., M.R.C.S., to Sarah Margaret, second daughter of Mrs. A. B. McKinley, of West Kirby, Cheshire.

DEATHS.

Armit.—On March 12th, in Sydney, Henry William Armit, M.R.C.S., L.R.C.P., Editor of the *Medical Journal of Australia*, younger son of the late William Armit, formerly Secretary to the Hudson's Bay Company, aged 59.

Fagan.—On Saturday, March 15th, at Highgate, Arthur Roberts St. Leger Fagan, M.R.C.S., L.R.C.P., in his 68th year.

Levick.—On March 8th, George Kenny Levick, M.B., B.S., of Havant, Hants, in his 62nd year.

Paton.—On March 11th, at Leighton Buzzard, Frederick Erskine Paton, M.B., of St Margaret's, Banbury-road, Oxford.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE TEACHING OF PARENTCRAFT.

At the annual meeting of the National Baby Week Council on March 12th Dr. H. K. Waller opened a discussion on the question: "How can a knowledge of parentcraft be extended to parents whom the existing welfare services do not reach?" He suggested the foundation of more clinics for subscribers, on the plan of the Babies' Club at Chelsea; the parents who attended the club were usually in a position to pay a subscription of £5 5s. yearly. An absence of poverty did not necessarily mean knowledge of mothercraft, and many of these women were interested in modern methods and anxious to learn. There was no reason to suppose that such clinics would interfere with the work of the family doctor, but it must be guaranteed by every clinic that only preventive measures would be discussed; mothers must be advised to take sick children to the family doctor. At the same meeting Mrs. Eva Hubback described a clinic of the kind which is to be opened at Hampstead Garden Suburb, and Dr. Margaret Emslie spoke of another where subscriptions were lower than those advocated by Dr. Waller, but which was not self-supporting. Mr. E. B. Turner reminded the Council that the representative meeting of the British Medical Association had expressed disapproval of these clinics. The family doctor with his knowledge of the parents and the home was, he said, the proper person to instil the principles of mothercraft. The subscription to the clinic would be better spent in summoning him for an equal number of attendances. Dr. D. H. Geffen replied that the general practitioner was not suited to carry on the work of the clinics, which included infant psychology, preparation of food, and knitting. The great object of such a clinic was to secure cases of illness early and to send them to the family doctor. In any event, nothing should be considered before the welfare of the mother and child, not even the position of the medical practitioner. Mr. Turner rejoined that a sufficient medical service would abolish the need for clinics entirely.

TONICO RAZOR PASTE.

Dr. F. W. Cory has called our attention to a preparation designed to give a keen edge to such articles as microtomes, lancets, and razors. It is described as non-abrasive and antiseptic and consists of two pastes, one to be used on the rough side of the strop for sharpening and the other on the smooth side for finishing. Dr. Cory speaks of a "tonic action" by which the "tired" metal is revived so that the instrument can be used every day without resting. The preparation which is marketed by Messrs. Osborne and Garrett, Frith-street, London, can be obtained from chemists and barbers.

HERO WORSHIP IN SURGERY.

To the Editor of THE LANCET.

SIR,—In the course of the Hunterian Oration (THE LANCET, Feb. 22nd, p. 390) Prof. Hey Groves makes the following statement. "We have also to deplore the loss of the last known descendant of the Hunter family in the person of Miss Helen Hunter Baillie, the great-grand-niece of John Hunter, who died in Feb., 1929, at the age of 86."

May I point out that this is incorrect. This great lady was the last of her generation—the third generation—but the children of her two married sisters are still alive and are great-great-grand-nieces of John Hunter. These are the children of Mrs. Oliver of whom four are alive, and the three daughters of Mrs. Maconechy. These are the fourth generation. The four children of Miss Muriel Maconechy—my wife—are the sole representatives of the fifth generation. The accompanying tree makes this descent more clear than it can be expressed in writing.

I am, Sir, yours faithfully,

Guildford, March 1st, 1930. T. B. JOBSON.

APPLES FOR DYSENTERY.

To the Editor of THE LANCET.

SIR,—Your article in THE LANCET of March 8th, pointing out how old popular remedies turn up again, and especially the revival of the use of apples in dysentery and typhoid, has a peculiar interest for me. When assisting at the epidemic of typhoid which occurred at Worthing towards the end of last century, I was called to see a patient—a strict vegetarian—who declined to be dieted in the ordinary way, but insisted on having large numbers of roasted apples. I anxiously awaited the outcome. The patient did so well that I began to adopt a similar diet in other cases with the most gratifying results. On my return to London I read a paper about the epidemic before the St. George's Hospital Hunterian Society, in which I pointed out that cases dieted in this way were very seldom constipated, and consequently that laxatives and enemata were hardly ever required; also that the patients were much less emaciated.

A few days after reading my paper my attention was drawn by Dr. Cyril Ogle to an article of Sir William Jenner's in which he had pointed out that the pulp of apple was an excellent thing for typhoid patients; in fact, that my treatment was an old remedy turning up again. May I add that I used to order the apples to be pulped and passed through a colander; that cream, whipped cream, or white of egg are useful adjuncts and a pleasant variety for the patient.

I am, Sir, yours faithfully,

JOHN W. DICKSON.

Sloan-terrace Mansions, S.W., March 11th, 1930.

NEW PREPARATIONS.

DIGINUTIN.—Messrs. Burroughs Wellcome and Co. are also placing a stable preparation of digitalis on the market, a solution of the total glucosides of digitalis leaf free from inert extractive matters. Specimens biologically tested after storage for more than a year retain their activity, a quality which in many circumstances is distinctly valuable and one which clinical reports confirm. Other advantages claimed for the preparation are that the physiological standardisation of the solution is particularly accurate owing to the absence of inert vegetable matter, while the fact of it being in solution aids in the rapid response to the drug.

BROSEDAN (Coates and Cooper, 41, Gt. Tower-street, London, E.C.).—This is a German preparation described as a yeast preparation containing sodium bromide. Its administration is quite simple, one to three teaspoonfuls being given in half a breakfast cup of hot water at bed time. The drug has been found to have sedative qualities in neurasthenia and many nervous manifestations, and specially in the course of the treatment of epilepsy. In this connexion it has received favourable notice from clinical workers and medical journals in Germany.

Corrigendum.—In the annotation last week on Pulmonary Tubercle of Bovine Type (p. 584) line 14 should read: "in culture and its *high* virulence . . ."

PEDIGREE OF
John Hunter of Long Calderwood.

Arris and Gale Lecture

ON THE RÔLE OF

SHORT CIRCUIT OPERATIONS IN THE TREATMENT OF CHOLECYSTITIS.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 1930,

BY R. H. O. B. ROBINSON, M.B. CAMB.,
FELLOW OF THE COLLEGE; SURGEON TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL; ASSISTANT SURGEON TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS.

ALTHOUGH notable advances have been made in the surgical treatment of inflammatory conditions affecting the bile passages and in our knowledge of the pathological changes at work, it must be admitted that there is still room for improvement, and this fact leads us to consider in what manner the results of our treatment are unsatisfactory and how this failure may possibly be remedied.

Before turning definitely to the subject of treatment there are certain points in connexion with the anatomy and physiology of the gall-bladder which should be borne in mind as well as some established facts concerning the pathology of inflammation in the biliary tract.

ANATOMY AND PHYSIOLOGY OF GALL-BLADDER.

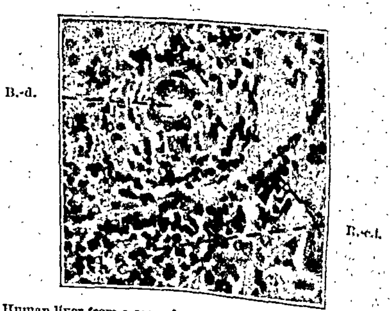
The gall-bladder, in common with the rest of the biliary apparatus, is developed as a diverticulum from the duodenum and possesses certain points of resemblance to it in structure and in function. The under surface of the body of the gall-bladder is in contact with the upper part of the duodenum and adjacent to the pyloric portion of the stomach. The neck and cystic duct pursue an S-shaped course toward the portal fissure, and the mucous membrane within this portion is thrown into from 5 to 12 concentric folds, the spiral valve of Heister. Mentzer,[1] of the Mayo Foundation, in an extensive study of its mechanism, could find no evidence of valvular action—that is to say, bile could pass with equal freedom in either direction—and Keith has pointed out that it is the very reverse of a valve, being an ingenious device to prevent any obstruction to inflow or egress consequent on kinking at the neck. The mucous membrane in the interior of the gall-bladder proper is thrown into numerous folds covered by a single layer of columnar epithelium and, as Boyd[2] has shown, these folds are so arranged that, on section, they appear as villi and may be spoken of as such, although strictly speaking not so, and further that this structure is suggestive of absorption. This absorptive power appears to be selective for water, salts, lipoids, and probably cholesterol.

Halpert,[3] working at the Johns Hopkins Hospital, has drawn attention to the fact that the muscle and elastic tissue of the organ resemble the muscularis mucosæ of the gut and suggests that they have a similar function—namely, to throw the mucosa into folds—and Boyden,[4] of Chicago, has drawn attention to the remarkable apparent increase in thickness of its wall consequent upon collapse of the organ by contrast with the condition it presents when distended. This point I shall refer to again later. Lastly, Kodama,[5] working with Graham, in a study of the lymphatic drainage of the gall-bladder, has shown that there is free communication between its lymphatics and those of the adjacent liver, the bile-ducts, the upper end of the duodenum, and the surface of the pancreas. The various activities of the intact gall-bladder are associated closely with the sphincter of the common bile-duct or sphincter of Oddi. It has been stated that in animals in which the gall-bladder is lacking, the sphincter is inadequate, and Judd and Mann[6] have suggested that this is so in the human subject after cholecystectomy, owing to increased pressure in the common bile-duct.

PATHOLOGY.

In considering the pathological changes of inflammation in the biliary tract it is convenient to include cholelithiasis with cholecystitis, for in cholecystitis calculus formation appears to be inevitable sooner or later, and in the vast majority of cases of cholelithiasis there is definite evidence of infection even if we allow that it is possible for a solitary stone to form in the absence of infection, although D. P. D. Wilkie[7] has recently produced evidence against such a process.

FIG. 1.



Human liver from a case of gall-stones showing a portal sheath with marked round-celled infiltration. B.-d. = bile-duct R.-c.i. = round-celled infiltration.

The pathological gall-bladder presents us with several problems which must be overcome if treatment is to achieve the best results. Firstly, it presents itself as a focus of infection, secondly as a factory of calculi, and thirdly as a potential site of carcinoma. To take these points in more detail, the gall-bladder may present itself to us during an attack of acute inflammation—in which event it forms one variety of acute intraperitoneal catastrophe—or as the site of chronic infection it may affect other parts of the biliary tract or provide a focus of generalised infection. It is well established that the gall-bladder when acutely inflamed compares very favourably with other intraperitoneal viscera—that is to say, peritonitis of any severity is rare—and that after an attack of acute inflammation under favourable circumstances the organ can return to almost its normal condition. The presence of fibrosis in the wall of the bladder need not necessarily interfere with its function any more than the scar of a whitlow need interfere with the function of a digit, or prove any greater argument for its removal. Unfortunately, however, in the case of such a cul-de-sac as the gall-bladder there is a tendency for the resultant fibrous tissue or associated calculi to interfere with function, producing stagnation and persistent infection. This infection is particularly marked in the outer coats, probably owing to the antiseptic properties of the bile in contact with the gall-bladder mucosa, as Rosenow[8] and A. L. Wilkie[9] have shown. The effects of this infection are by no means limited to the gall-bladder, as might indeed be presupposed from a knowledge of its lymphatic drainage, and thus we find in many—and if we accept some authorities in all—cases of cholecystitis changes in other parts of the biliary tract. In the liver, especially that part adjacent to the gall-bladder, but also widespread in the hepatic portal sheaths as stressed by Graham[10] and by Judd[11] and evidenced macroscopically in many cases by scarring on the surface of the li in the bile-ducts as pointed out by Burden [12] and affecting the pancreas as shown by Deaver and Sweet [13] and by Graham.[14] One might point out in this connexion that little information is extant about the fate of these associated lesions following cholecystectomy. How common infective changes are outside the gall-bladder itself is shown by the fact that in 281 cases of cholelithiasis which I [15] investigated and in which stones were limited to the gall-bladder jaundice occurred at some stage in 36 per cent. Fig. 1 shows well-marked infective changes in the hepatic portal sheaths in a subject suffering from stones limited to the gall-bladder and treated by cholecystectomy.

The actual path of infection to the biliary tract has been the subject of much research and discussion, and it appears that the lymphatic route and the hæmatogenous, as pointed out by Moynihan[16] and D. P. D. Wilkie,[7] are the most usual. But Moynihan has called attention to the additional possibility of direct infection up the common duct in the presence of achlorhydria with consequent increase of intestinal flora.

When we come to consider the gall-bladder as a factory of calculi we find again that this point is bound up with the question of infection. It is probable that all calculi, even the solitary stone, are the product of inflammatory changes. However, if stasis is prevented and free drainage is provided, calculus formation should prove impossible owing to the prevention of cholesterol accumulation and the prompt removal of biliary grit even if formed. This is important, for such particles are capable of increase in size and the production of obstruction throughout the biliary tract.

The last fact in the pathology of the gall-bladder, to which I shall refer, is that it is a potential site of carcinoma; but this seems to be so definitely associated with the presence of antecedent inflammation and calculus formation that if chronic irritation is avoided it is unlikely to occur and in actual fact carcinoma of the gall-bladder is not as common as is usually supposed.

The treatment of cholecystitis, then, must consist in abolition of persistent infection within the biliary tract—though not necessarily in abolition of the aftermath of infection—and in the removal of calculi and the prevention of further calculus formation. By dealing with these two points the possibility of carcinoma will be avoided.

TREATMENT.

In the treatment of cholecystitis I think there is general agreement that it is only by surgical intervention, in all but the mildest cases, that we can hope to give material benefit, and surgical treatment has consisted, speaking generally, of draining or removing the gall-bladder.

Drainage of the gall-bladder, or cholecystostomy, was the first operation undertaken and for a time enjoyed an uninterrupted vogue. Let us consider how it deals with the problems I have discussed and in what ways it fails to do so.

The inevitable drawback to the operation is that it is a purely temporary measure. By draining an inflammatory focus the operation relieves congestion and stasis, makes possible the removal of calculi, and, if the cystic duct is still patent, drains for a time the biliary tract, having a beneficial effect on associated cholangitis and retention of biliary excretion. Once the fistula closes, however, it leaves, as a rule, a gall-bladder with the factors that caused the original symptoms still operative, so that in many cases symptoms of greater or less severity recur, produced by persistent infection, or by fresh calculi. If when drainage is carried out the cystic duct has been obliterated completely, a mucous fistula will almost certainly be the result, and this will not heal without further operation. However, it must be admitted that, provided the cystic duct is patent, during the period of drainage the effect of the operation is good. These points are brought out by the following statistics: Taking 174 cases treated by cholecystostomy in St. Thomas's Hospital in the years 1911–28 inclusive, and in which the after-history could be ascertained, 49 per cent. remain cured up to date, 22 per cent. relieved, that is to say, benefited but still suffering some digestive disturbance, and 29 per cent. must be accounted failures. Of these unsatisfactory cases 35 have re-entered the hospital for further operative treatment, the secondary operations revealing the following conditions: Acute cholecystitis 3 cases, 1 without stones, 1 with stones in the gall-bladder, and 1 with stones in bile-duct; chronic cholecystitis 31 cases, 8 without stones, 14 with stones in the gall-bladder, 7 with stones in the common bile-duct, and 2 with pancreatitis; carcinoma of the gall-bladder, 1 case.

It was largely owing to the very high percentage of unsatisfactory results following cholecystostomy, to the more intensive study of the underlying pathology, and to the appreciation of the fact that cholecystectomy in skilled hands is no more dangerous, that cholecystectomy became the operation of choice. In confirmation of the statement that cholecystectomy is no more dangerous than cholecystostomy, the following figures at St. Thomas's Hospital, though admittedly few in number, may be given. 146 cases of cholecystostomy, amongst which acute cholecystitis was present in 16 per cent. and gross chronic cholecystitis—that is to say, of such severity as to render the operation technically difficult—in 56 per cent. showed a mortality of 9 per cent., whilst 80 cases treated by cholecystectomy, amongst which acute cholecystitis was present in 23 per cent. and gross chronic cholecystitis in 75 per cent., showed a mortality of 6 per cent., and a further series of 97 cholecystostomies and 315 cholecystectomies show a similar result. It is of interest to note the complete reversal of the ratio of frequency of the two operations in late years.

Cholecystectomy deals radically with the possibilities of a focus of chronic infection, and of a factory of calculi, but unfortunately, in many cases, we shall be locking the stable door after the horse has gone, and the evils produced by the gall-bladder while in situ will remain. Mere removal of the gall-bladder may do little to remedy associated cholangitis or pancreatitis, and thus we find after cholecystectomy a definite proportion of unsatisfactory results. Thus 176 cases treated by cholecystectomy show 73 per cent. as cured, 16 per cent. as relieved, and 11 per cent. as failures. This percentage is composed of cases of pancreatitis acute and chronic, of obstructive jaundice due to inflammation or calculi, and of biliary colic. Similar figures are seconded by Whipple, by Müller,[17] and by Rowlands.[18] The figures for cholecystectomy show a definite improvement over those for cholecystostomy, and are comparable if either operation is combined with exploration of the common bile-duct. The actual cause of failure in these cases, then, may be the presence of stones in the bile-ducts, stenosis of the ducts, or persistent cholangitis and pancreatitis, and it follows that when any of these conditions are found or suspected at the original operation, very serious consideration must be given to the advisability of removing the gall-bladder. It has been shown by Burden,[12] and by Judd and Counsellor, all of the Mayo Clinic,[19] that cholecystitis is nearly always accompanied by cholangitis of the chronic inflammatory type which is ultimately productive of stricture and is likely to influence the result of operations for the relief of common duct obstruction, and explains the frequency with which incomplete intermittent obstruction follows plastic operations for the relief of strictures of the bile-ducts (see Fig. 1). Cases manifesting recurrence of symptoms after cholecystectomy constitute one of the most difficult problems in surgery. As a result of impaired function of the liver the patients are seldom good operative risks; the presence of obstructive jaundice introduces the danger of serious hæmorrhage, and the technical difficulties of identifying the diseased structures may be very great owing to the presence of adhesions and the fact that the natural signpost to the ducts—namely, the gall-bladder—is lacking. When ultimately the knot is unravelled the problem of what can or what ought to be done has still to be faced. In such cases Walters,[20] from his work in the Mayo Clinic, considers that the successful treatment of strictures in the bile-ducts depends on the presence of enough duct on the proximal side of the stricture to permit of accurate anastomosis to an opening in the duodenum as well as that a minimal amount of infection should exist in the biliary passages, but that, in view of the frequent infection present, recurrent symptoms of intermittent obstruction are likely. Judd [21] agrees with these views, and points out that in certain cases in which the segment distal to the stricture is located readily and appears healthy, end-to-end anastomosis of the duct is preferable, but that the anastomosis should be performed over a Kehr Deaver T-tube allowing of prolonged drainage of bile to the exterior, a point he regards as essential. If the operation of anastomosis of an hepatic duct to the alimentary canal proves impracticable, the only possibility is the production of an external biliary fistula followed by an attempt subsequently to dissect out and anastomose the fistulous track to the gut as described by Lahey,[22] of Boston. In all cases prolonged drainage is to be aimed at, and after any of these complex and difficult operations a recurrence of symptoms is to be feared. The desirability of drainage in such cases has been emphasised in this country by Moynihan. In view, therefore, of this opinion that in all cases where the common duct is or is likely to become obstructed, with consequent biliary stasis, a long period of drainage or even permanent drainage is desirable and that, in all cases in which the cystic duct remains patent, the gall-bladder offers the possibility of permanent drainage, would it not be sound practice to utilise it in a short circuit? After such a short circuit, stasis within the biliary tract seems unlikely, and consequently calculus formation is improbable. In the absence of calculi carcinoma is exceedingly rare, and the abolition of stasis by free drainage should have a beneficial effect on latent infection throughout the biliary tract and upon hepatic function.

By the term short circuit we can be taken to mean the operations of cholecystgastrostomy and cholecystduodenostomy as anastomosis to the rest of the small bowel or colon are more difficult to perform and more divergent from the normal anatomy of the biliary tract.

The suspicion with which short circuit operations are regarded is undoubtedly due to the fact that they have been performed almost entirely in cases of obstructive jaundice due to malignant disease in the head of the pancreas, and the figures showing the survival period after the operation under such conditions are certainly not encouraging. Thus the proven cases, 25 in number, operated on in St. Thomas's Hospital during the last nine years, all succumbed within nine months of operation, and 17 within six weeks. Undoubtedly not enough attention has always been paid to technical details such as the preoperative preparation of the patient against the risk of hæmorrhage, but if the patients survive the operation their condition is greatly alleviated as pointed out recently by Walters and McVicar,[23] and death is due to spread of carcinoma and interference with the pancreatic function and in no sense to the short circuit operation as such.

If we examine the results of this type of operation when carried out for the relief of inflammatory conditions in the bile passages we find a very different state of affairs. I have collected all the cases I could find of this type, 18 in all, performed at St. Thomas's Hospital, and all having been performed since 1923; in more than half the operations were done by me personally and all the patients are alive and well, whilst the majority are cured completely of their symptoms. Further, experimental animals can be maintained in perfect health and condition after such an operation. Having established the fact then that, speaking generally, the results of a short circuit when performed for the relief of an inflammatory lesion are good, let us consider in detail any theoretical or established objections to the procedure taking the various points seriatim.

In the first place it has been doubted whether it is possible to produce a permanent and adequate anastomosis between the alimentary canal and the gall-bladder, unless the common bile-duct is obstructed completely, a state of affairs not likely to be the result of inflammation. I have had an opportunity of observing two cases, one five months and one two years after operation, and in each case the stoma was as large as when made and the same is true in experimental animals. I feel sure that an opening that will admit the little finger is desirable, and both Deaver and Wangensteen [24] of Minneapolis, strong advocates of the operation, consider an adequate anastomosis very important as otherwise cholangitis is liable to persist.

The second point is the practicability of utilising the gall-bladder for the formation of an anastomosis seeing that in these cases the gall-bladder will be diseased. Obviously it is essential that the continuity of the cystic duct should not have been destroyed, for if so the operation will be useless. The presence of inflammation in the gall-bladder is no bar to the operation provided the condition has not progressed to the extent of gangrene. In one of my own cases acute cholecystitis was present consequent on the impaction of a stone in the neck of the gall-bladder. On tapping it and pushing back the impacted stone, the condition of the viscus improved at once as shown by free bleeding and change in colour. An anastomosis was therefore made with the stomach, and the patient made an uninterrupted recovery and was so well satisfied with her condition that, three years later, she advised her mother, aged 70, to come to London from a considerable distance because she also suffered from cholelithiasis. A microscopic section of the gall-bladder wall in this case showed it to be densely infiltrated with polymorphonuclear leucocytes. Chronic inflammation, unless accompanied by gross fibrosis or destruction of the mucous membrane, does not make the operation impracticable and, in this connexion, it may be remembered that the mucous membrane is often surprisingly little affected.

Thirdly, it has often been stated that after a cholecystgastrostomy the presence of bile in the stomach gives rise to nausea or even vomiting from gastric irritation. In all my personal cases and in those which have come under my observation, vomiting has been conspicuous by its absence. This, however, leads us to a more important point—namely, the effect of bile present in the stomach on gastric function. I have investigated gastric curves in five cases after cholecystgastrostomy and these are all within the normal range and correspond to the preoperative curves, although the resting juice in every case and the subsequent samples in most were stained with bile. This fact has been noted by other observers—namely, Oddi,[25] Dastre,[26] so long ago as 1888–90, and more recently in America by Beaver,[27] Grey,[28] and others. Here it should be noted that it seems unlikely that the operation can have any beneficial effect in the treatment of gastric ulcer as has been claimed.

The next point that suggests itself is that even if the passage of bile into the stomach has no effect on gastric function, is the converse equally true that contact with the gastric mucosa has no effect on bile as a participant in fat metabolism? I have not been able to detect any interference with fat metabolism in experimental animals previously subjected to a short circuit even in the presence of total obstruction of the common bile-duct by ligature carried out at the same time, the amount of fat in the fæces and the percentage of split fat being quite normal. Clinically there is no evidence of impaired fat digestion in cases of inflammatory disease, but this is in contrast with what occurs in the bile-ducts as pointed out by Burden[12] and affecting the pancreas as shown by Deaver and Sweet[13] and by Graham.[14] One might point out in this connexion that little information is extant about the fate of these associated lesions following cholecystectomy. How common infective changes are outside the gall-bladder itself is shown by the fact that in 281 cases of cholelithiasis which I[15] investigated and in which stones were limited to the gall-bladder jaundice occurred at some stage in 36 per cent. Fig. 1 shows well-marked infective changes in the hepatic portal sheaths in a subject suffering from stones limited to the gall-bladder and treated by cholecystectomy.

The actual path of infection to the biliary tract has been the subject of much research and discussion, and it appears that the lymphatic route and the hæmatogenous, as pointed out by Moynihan[16] and D. P. D. Wilkie,[7] are the most usual. But Moynihan has called attention to the additional possibility of direct infection up the common duct in the presence of achlorhydria with consequent increase of intestinal flora.

When we come to consider the gall-bladder as a factory of calculi we find again that this point is bound up with the question of infection. It is probable that all calculi, even the solitary stone, are the product of inflammatory changes. However, if stasis is prevented and free drainage is provided, calculus formation should prove impossible owing to the prevention of cholesterol accumulation and the prompt removal of biliary grit even if formed. This is important, for such particles are capable of increase in size and the production of obstruction throughout the biliary tract.

The last fact in the pathology of the gall-bladder, to which I shall refer, is that it is a potential site of carcinoma; but this seems to be so definitely associated with the presence of antecedent inflammation and calculus formation that if chronic irritation is avoided it is unlikely to occur and in actual fact carcinoma of the gall-bladder is not as common as is usually supposed.

The treatment of cholecystitis, then, must consist in abolition of persistent infection within the biliary tract—though not necessarily in abolition of the aftermath of infection—and in the removal of calculi and the prevention of further calculus formation. By dealing with these two points the possibility of carcinoma will be avoided.

TREATMENT.

In the treatment of cholecystitis I think there is general agreement that it is only by surgical intervention, in all but the mildest cases, that we can hope to give material benefit, and surgical treatment has consisted, speaking generally, of draining or removing the gall-bladder.

Drainage of the gall-bladder, or cholecystostomy, was the first operation undertaken and for a time enjoyed an uninterrupted vogue. Let us consider how it deals with the problems I have discussed and in what ways it fails to do so.

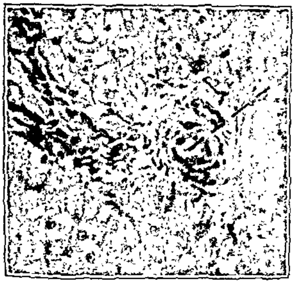
The inevitable drawback to the operation is that it is a purely temporary measure. By draining an inflammatory focus the operation relieves congestion and stasis, makes possible the removal of calculi, and, if the cystic duct is still patent, drains for a time the biliary tract, having a beneficial effect on associated cholangitis and retention of biliary excretion. Once the fistula closes, however, it leaves, as a rule, a gall-bladder with the factors that caused the original symptoms still operative, so that in many cases symptoms of greater or less severity recur, produced by persistent infection, or by fresh calculi. If when drainage is carried out the cystic duct has been obliterated completely, a mucous fistula will almost certainly be the result, and this will not heal without further operation. However, it must be admitted that, provided the cystic duct is patent, during the period of drainage the effect of the operation is good. These points are brought out by the following statistics: Taking 174 cases treated by cholecystostomy in St. Thomas's Hospital in the years 1911–28 inclusive, and in which the after-history could be ascertained, 49 per cent. remain cured up to date, 22 per cent. relieved, that is to say, benefited but still suffering some digestive disturbance, and 29 per cent. must be accounted failures. Of these unsatisfactory cases 35 have re-entered the hospital for further operative treatment, the secondary operations revealing the following conditions: Acute cholecystitis 3 cases, 1 without stones, 1 with stones in the gall-bladder, and 1 with stones in bile-duct; chronic cholecystitis 31 cases, 8 without stones, 14 with stones in the gall-bladder, 7 with stones in the common bile-duct, and 2 with pancreatitis; carcinoma of the gall-bladder, 1 case.

It was largely owing to the very high percentage of unsatisfactory results following cholecystostomy, to the more intensive study of the underlying pathology, and to the appreciation of the fact that cholecystectomy in skilled hands is no more dangerous, that cholecystectomy became the operation of choice. In confirmation of the statement that cholecystectomy is no more dangerous than cholecystostomy, the following figures at St. Thomas's Hospital, though admittedly few in number, may be given. 146 cases of cholecystostomy, amongst which acute cholecystitis was present in 16 per cent. and gross chronic cholecystitis—that is to say, of such severity as to render the operation technically difficult—in 56 per cent. showed a mortality of 9 per cent., whilst 80 cases treated by cholecystectomy, amongst which acute cholecystitis was present in 23 per cent. and gross chronic cholecystitis in 75 per cent., showed a mortality of 6 per cent., and a further series of 97 cholecystostomies and 315 cholecystectomies show a similar result. It is of interest to note the complete reversal of the ratio of frequency of the two operations in late years.

Cholecystectomy deals radically with the possibilities of a focus of chronic infection, and of a factory of calculi, but unfortunately, in many cases, we shall be locking the stable door after the horse has gone, and the evils produced by the gall-bladder while in situ will remain. Mere removal of the gall-bladder may do little to remedy associated cholangitis or pancreatitis, and thus we find after cholecystectomy a definite proportion of unsatisfactory results. Thus 176 cases treated by cholecystectomy show 73 per cent. as cured, 16 per cent. as relieved, and 11 per cent. as failures. This percentage is composed of cases of pancreatitis acute and chronic, of obstructive jaundice due to inflammation or calculi, and of biliary colic. Similar figures are seconded by Whipple, by Müller,[17] and by Rowlands.[18] The figures for cholecystectomy show a definite improvement over those for cholecystostomy, and are comparable if either operation is combined with exploration of the common bile-duct. The actual cause of failure in these cases, then, may be the presence of stones in the bile-ducts, stenosis of the ducts, or persistent cholangitis and pancreatitis, and it follows that when any of these conditions are found or suspected at the original operation, very serious consideration must be given to the advisability of removing the gall-bladder. It has been shown by Burden,[12] and by Judd and Counsellor, all of the Mayo Clinic,[19] that cholecystitis is nearly always accompanied by cholangitis of the chronic inflammatory type which is ultimately productive of stricture and is likely to influence the result of operations for the relief of common duct obstruction, and explains the frequency with which incomplete intermittent obstruction follows plastic operations for the relief of strictures of the bile-ducts (see Fig. 1). Cases manifesting recurrence of symptoms after cholecystectomy constitute one of the most difficult problems in surgery. As a result of impaired function of the liver the patients are seldom good operative risks; the presence of obstructive jaundice introduces the danger of serious hæmorrhage, and the technical difficulties of identifying the diseased structures may be very great owing to the presence of adhesions and subsequently. The site of anastomosis corresponded closely to that made in the human subject—that is to say, in the case of a gastrostomy a point on the anterior surface of the pyloric antrum. In the case of duodenostomy the opening was relatively comparable, being proximal to the entrance of the common bile-duct into the duodenum. The relative size of the stoma was also strictly comparable, being about a sixth of an inch in diameter in the case of the cat.

The microscopical findings at the time the animals were killed can be considered throughout the various parts of the biliary tract. In the gall-bladder itself, particularly near the stoma, there is definite thickening of the wall and more than would be accounted for by mere collapse of the viscus. Examine the photographs showing a normal cat's gall-bladder in the state of distension and a similar bladder in the state of collapse. There is apparent thickening due to contraction as pointed out by Boyden. Fig. 3 shows a gall-bladder removed one year after cholecystgastrostomy which was performed in January, 1928, and the animal killed in January, 1929. Three things are noticeable. First, the tremendous hypertrophy of the unstriped muscle; secondly, the deepening of the mucous membrane; and, thirdly, the absence of inflammation. The hypertrophy of muscle is more obvious even in sections stained by Mallory's method and presumably due to submission of the gall-bladder to the peristaltic pressure of the stomach. The deepening of the mucous membrane is very marked near the anastomosis and is shown in Fig. 4, when on the one hand we have gastric mucosa and on the other hypertrophic gall-bladder mucous membrane. This last point has been noted previously by Smith [41] of St. Louis. The absence of inflammatory reaction is shown by examination under a higher power.

FIG. 5.

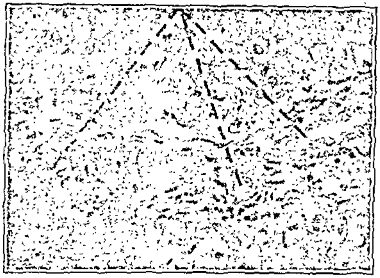


Normal cat's liver, showing a portal sheath. B.-d. = bile-duct.

Bacteriological examination in these experiments was of interest, for whereas culture from the gut and lumen of the gall-bladder showed growth of *Bacillus coli* and streptococci, the wall of the gall-bladder and cystic duct, and also the liver in both the peripheral and deeper portions, including the larger bile-ducts, proved sterile on culture in serum glucose broth both aerobically and anaerobically.

When the effect on the liver itself was studied the microscopic appearances were normal and microscopically as a rule nothing abnormal could be detected. Fig. 5 shows normal liver with one of the small hepatic portal sheaths and Fig. 6 a similar specimen from a cholecystgastrostomy, the animal being killed twelve months subsequently. These may be contrasted with Fig. 1 taken from a human liver in a subject suffering from cholecystitis. In one case of cholecystgastrostomy and ligature of the common bile-duct some changes in the portal sheaths appeared to be present, but even in this case the liver and walls of the biliary passages were sterile in culture, although the mucous membrane showed catarrhal inflammation. This is in very sharp contrast with the experimental results reported in America, where gross infection was the rule, and accords more with the reported good clinical results.

FIG 6.



Cat's liver 12 months after cholecystgastrostomy.
B.-ds. = bile-ducts.

I would claim, therefore, that after the short circuit operation there is no bacteriological or gross histological evidence of ascending cholangitis, although it is possible that this may occur as a transitory phase during convalescence from the operation, or in the presence of complete obstruction of the common bile-duct, and, incidentally, total obstruction is never produced by inflammatory changes. I hope to undertake further experimental work on this point.

Judd,[42] in a consideration of the results of side-tracking operations, states "that infection is not as apparent clinically as might be expected from a study of experimental animals after operation, and that in the cases in which the gall-bladder has not been removed and in which the cystic duct is patent so that there is bile in the gall-bladder, the preferred operation is cholecystgastrostomy. This operation can be carried out easily." I can corroborate this. Whipple [43] of New York records similar experience.

TECHNIQUE OF OPERATION.

As regards the actual technique of a short circuit operation in man, the best exposure is obtained by an incision through the sheath of the right rectus muscle with outward displacement. In the majority of cases cholecystgastrostomy will be the operation of choice as an adequate stoma—that is to say, one admitting the little finger—can be made, and the anastomosis can be performed outside or flush with the abdominal wound, permitting of adequate packing off from the general peritoneal cavity. This is an important point because after incision of the gall-bladder infected bile and stones will have to be evacuated. Personally I never use clamps as I find them a hindrance and apt to damage the delicate tissues, and I use two layers of continuous sutures, the inner being inserted in the manner described by Connell. Performed in this way the anastomosis should be perfectly secure, and it is unnecessary and definitely inadvisable to tack omentum to the suture line. The actual site of the stoma is found to lie most conveniently on the anterior surface of the pyloric antrum about an inch to the left of the pylorus.

In certain cases where the patient is thin or the duodenum mobile cholecystduodenostomy will be found equally easy to perform, but owing to the limited peritoneal coverings of the duodenum it will be found impossible to make as large a stoma, the size of a lead pencil being the largest possible and the anastomosis will lie in close juxtaposition to the pylorus. I always close the abdomen in layers without drainage, and in the human subject have never experienced any leakage at the suture line. In experimental animals the gall-bladder is so thin that it is impossible to insert a truly sero-serous stitch which does not transgress the lumen at any point and for this reason I have had trouble from leakage in two experiments. In man radiograms taken subsequently have failed to demonstrate any pyloric deformity or delay six months after the operation, by which time any cicatrisation likely to supervene should have occurred. Unless it is obvious that cholecystduodenostomy can be performed with ease and safety, I should say that cholecystgastrostomy is the operation of choice. The convalescence of these cases is remarkably smooth, the average duration of stay in hospital after the operation being 18 days; there is no need for frequent dressings and there is no loss of bile to the exterior with consequent impairment of nutrition. The risk appears to be small as I have collected 18 cases without a fatal result. Stasis in the biliary tract is avoided and a permanent safety valve provided. Associated lesions, such as a stone in the common bile-duct, if removable, should be dealt with at the same time.

The Table shows in some detail a summary of the 18 cases of short circuit performed for inflammatory conditions in the bile passages. I would emphasise again that these 18 cases are not in any sense selected but represent all the authentic cases of short circuit for inflammatory conditions performed at St. Thomas's Hospital I could collect. The mortality was nil and the end-results up to date give as cured and two as relieved, while none are definitely failures.

Eighteen Cases of Short Circuit of Cholelithiasis.

Case.	Sex.	Age.	Length of history in years.	Jaundice.	Nature of symptoms.	Operation findings.	Date of operation.	Type.	Result.

Cc. = cholecystostomy. Cg. = cholecystgastrostomy. Cd. = cholecystduodenostomy. A. colic = attacks of colic. Panc. = pancreatitis. St. = stones. G.-b. = gall-bladder. C.b.-d. = common bile-duct. C. = cured. R. = relieved.

One of the cases relieved was an early case in which I tacked the omentum round the anastomosis and the patient also suffered considerable post anæsthetic bronchitis as a result of which there must have been partial failure of union in the peritoneal suture line. Dense adhesions formed, obstructing the pyloric end of the stomach and necessitating laparotomy for their division; from the point of view of the biliary tract the result appeared good. The gall-bladder wall was soft and supple, the stoma unchanged. The patient expresses herself, three and a half years later, as definitely improved, has gained over a stone in weight, and when I saw her recently appeared to merit the description of cured. The other case was one which the doctor describes the patient as still suffering dull pain in the stomach, but otherwise the condition is good. In this series you will see there were 13 cholecystgastrostomies and five cholecystduodenostomies, and that in 11 there was clinical evidence of cholangitis—that is to say, jaundice before operation—and corroborated by microscopic changes in the ducts at operation in 7.

CONCLUSIONS.

What place in the treatment of inflammatory conditions of the bile passages should a short circuit operation occupy? I think it fair to say that in all cases where obstructive changes are present or suspected or are deemed likely to supervene in parts of the biliary tract other than the gall-bladder permanent relief of symptoms is produced. My own results lead me to favour the view that where the gall-bladder is comparatively healthy except for the presence of calculi and the cystic duct is patent, it should prove the operation of choice in cholangitis, in stricture, and in any case where the head of the pancreas is found to be hard. Published statistics of other operations undertaken for similar conditions after removal of the gall-bladder has been previously carried out are not so satisfactory. Although some authorities produce experimental evidence of invariable infection in experimental animals there is no clinical evidence of this, and I have carried out experiments in animals without producing demonstrable infection. I have carried out the operation in man with success and the absence of any clinical evidence of subsequent infection in cases where disease was considered to be localised to the gall-bladder alone. But in view of the conflicting opinions as to the risks and degree of ascending infection, I think further evidence must be obtained before the operation can be regarded as an alternative to cholecystectomy for this type of case.

In conclusion, I should like to thank Dr. T. H. Wilson, my house surgeon, who made the microphotographic preparations; Dr. W. J. Griffiths, who carried out or supervised the chemical investigations; and, above all, Sir Cuthbert Wallace for his encouragement and for giving me the facilities of the Surgical Unit.

ATHLETICS IN SCHOOLS.

Introducing a Discussion at the Hunterian Society on March 24th

BY LANCELOT R. LEMPRIERE, O.B.E.,
B.A. OXF., M.B. VICT.,
RESIDENT MEDICAL OFFICER, HAILEYBURY COLLEGE.

I RECOGNISE that you want from me the facts and experiences of my 27 years' service as a public school medical officer, covering the medical and athletic records of over 4500 boys, and though statistics may be the refuge of the intellectually destitute, they may have their uses. I may find it difficult to avoid the athletic standpoint, as I have had a humble though lifelong active participation in all school sports, except rowing, boxing, and long-distance running.

Challenging Voices.

It is rather over twenty years ago since the question of abuse of games and runs in schools was fully discussed by the Medical Officers of Schools Association, owing to a letter in the public press, signed by four of the most eminent doctors of the day, condemning all runs of over one mile in length. The result of a two days' debate was a general approval of the way games and the like were managed. We have possibly lived in complacent self satisfaction, I hope not in a fools' paradise, since then, and it is an excellent thing that we should once again review our actions and policy, the more so as history has repeated itself and, a year ago, another very distinguished member of the profession made a sweeping attack in the public press on the management or rather want of management of sports and athletics in public schools. The charges made were so serious, that I and several of my colleagues wrote and challenged the accuracy of the article, and received the reply that the statements did not apply to us personally. As this article bears directly on to-night's discussion, I will quote from it:—

> "So many instances of the very deleterious results of excessive exercise upon both girls and boys have come under observation recently, that it seems advisable that some definite control should in future be exerted upon the amount of exercise which each pupil shall, after adequate examination, be considered capable of, on entry into school.
>
> "That the headmaster or mistress should exert this control of exercise is utterly ridiculous, and the many examples of serious harm, and in one instance of death, which have resulted in consequence of excessive exercise in individual cases, shows that the question of games and exercises urgently calls for the closest attention.
>
> "The craze for games in our public schools is carried to a ridiculous length, and the powers of a headmaster to order a growing boy, who does not play cricket or football, to run as many as seven miles a day is simply intolerable.
>
> "In several instances, in consequence of this overstrain in growing lads or girls in important public schools . . . the health or even the lives of the pupils have been endangered or permanently deteriorated."

The writer goes on to compare our system unfavourably with that adopted in other countries. Now the fact, which is I believe unique, that games are compulsory in public schools in England, makes it all the more important to meet if possible this charge, based apparently on definite facts. I have therefore reinforced my own experience by that of the medical officers of 30 of the large public schools, embracing over 16,000 boys, and covering periods of from 3 to 30 years.

Exercise of Control.

The first point is the amount of control exerted by the school medical officer. This necessarily varies, according as the medical officer is whole or part time, but with one exception, all my correspondents express themselves as satisfied with their powers of control and management. Indeed, quite a number speak of absolute power of veto and complete control. It is also true that our advice is sought and generally followed on many aspects of school games, while so much care is taken for the weakly individual that it might be said of us: "So careless of the type we seem, so careful of the single life."

At the same time, it is equally true to say that changes, not necessarily for the good, can readily creep in without our knowledge, and it is of course also true that we are all of us liable to make mistakes or errors of judgment. Boys are just as foolish as we were, and perhaps more emancipated, and they need constant watching, as regards the regulations they make. Arm-chair administration or supervision will certainly allow abuses to develop, and constant observation on the part of the medical officer is the only real safeguard.

There is one school, in which the medical officer of several years' standing (who has since retired) states that he had no control, that his advice was not sought, that there was no proper supervision over training, that boys overtrained hopelessly, that frequent fainting had occurred on long cross-country runs, and that games began immediately after meals. It is true that nothing disastrous had happened so far.

Fatalities.

These are surprisingly few—a total of six in the last 20 years. Of these, four were pure accidents: one diving from a forbidden height, one fractured skull from a cricket ball, one palmar abscess and septicæmia also from a cricket ball, one ascending myelitis following a football injury. The fifth was a sudden death on the football field in a previously healthy boy two hours after his dinner. Post mortem nothing abnormal was found either macro- or microscopically, but there was undigested food in the stomach. The sixth case is considered doubtful by the reporting medical officer. A boy who had had slight tonsillitis, high-jumped eight days later, and ran a short race ten days later; he developed heart symptoms, and died seven months afterwards from infective endocarditis.

Very near to death were two cases of fractured cervical spine which both recovered, and the remarkable cases of a depressed fracture of the skull at football, which was immediately taken to hospital, operated on, and was back in bed before the end of the game. Quite recently a case was reported of a girl of 15 who died suddenly on the hockey field, the coroner recording a verdict of heart failure following exercise after a heavy meal.

Disability.

The next question concerns severe disabilities—i.e., those causing long or even permanent incapacity. Here one is on much less sure ground, owing to the different value that may be attached to the word "severe"; but 25 schools record no known instance, and five others record ten cases: of these six followed rowing, and four followed cross-country running—two of the latter being boys who had recently had mild influenza.

I had myself remembered and known of no such cases, but wrote to some 30 old boys, of whom I had records of cardiac disability, in which school exercise might have been a factor. With one exception, all who replied, 20 in number, said that they had been all the fitter for their school exercise, and several of them reported a very strenuous after-life, such as boxing for years for a living, prospecting, digging for oil, winning a competitive 45-mile walk, hunting big game, and active service in the Army. The single case is that of a man who came to the school with a previous history of rheumatic fever, who attributes his breakdown to a three-mile run. He was taken away from school and has undoubtedly been permanently affected. This was 27 years ago, just after I went to the school.

I also wrote an open letter to the school magazine, asking any old boy who considered he had suffered any ill-effects as the result of the exercise at school, to write to me: I have had a number of answers, but all of them so far praising the system, and stating that they derived nothing but benefit. Such a negative reply may not of course be worth much.

Possible Abuses.

So far I have referred to the past, but my last question to myself and my colleagues was about possible abuses, such as excessive amount of exercise, unequal grouping both of age and physique, short time after meals or playing games too soon after some illness.

Excess.—Whether it is a sign of advancing years, or of increased experience, I know not, but I do feel that there is some evidence of the intemperance of physical exercise. To be "cock house" is the overriding ambition of the average healthy-minded, and in the autumn and spring terms he will do much to secure this. The intemperance shows itself, not in a complete breakdown, but more in general fatigue and lassitude, loss of weight, diminished and inferior intellectual output, crying out for less work, both mental and physical. This condition is seen in the strong robust types, not seldom in the heads of houses or XVs., who have a very full life; it is not serious in them and soon recovered from, but it more serious and important in the young promising athlete. The above symptoms are also often seen in cases of slight concussion, which have not been reported or noticed at the time.

Football is now the tyrant. Immature house captains may be veritable slave-drivers, and their partisan zeal, or as Dukes said: "The enthusiastic impulses of exuberant youth," praiseworthy from many points of view, and not infrequently shared by young and keen house masters, may, I feel sure, lead to excess, and the young colt of under 16 in particular does need safeguarding, not only for his own health, but also, if I may so, for the good of his own game, and therefore for his house. From this point of view, I have long urged what I call the N.C.C., that is, an occasional "non-compulsory changing day," when a boy need only play or take exercise if he wants, not because he must. I am glad to find that this is advocated by some other school medical officers.

Runs, both road and cross-country, have undergone a remarkable change in my experience. Twenty-five years ago, runs of 1¾ and 3 miles were the shortest; they might be run three or four times a week, and the younger the boy, the more often he ran them. Cross-country runs were in vogue. Nowadays these 1¾ and 3-mile runs are the longest routine runs; they are run much less often, and one of the present usual exercise runs is rather less than a mile on grass with posts fixed at varying intervals for mixed sprinting and walking. This was introduced to diminish the number of deadly dull road runs, so generally disliked, and also to try to increase our pace, in which, as a school we are deficient (due partly to this, and also to our clay soil which makes for endurance rather than for speed). I think we have cut out runs too much, especially for the bigger boys for training purposes; the more so, as I have never seen any harm from them (except for the one case quoted previously) except to the feet. And here I must protest against the use of heelless gym shoes for road runs by young boys. This is definitely harmful, and dropped arch, and bruised and painful heels are a common result.

To the parent, however, the school run still seems to imply a 5 to 10-mile run at racing speed over difficult country, probably spurred on by some stern prefect, and I am still being often asked by them or the home doctor to give leave off. As a matter of fact, asthmatics are about the only ones who should be excused.

The *competitive steeplechase* is totally different. As with all other sports, it is primarily a house concern, and six picked boys from each house enter. The distance is about 3½ miles over a difficult and heavy country, and is undoubtedly a great test of endurance. The increased difficulties of the course have gone hand in hand with the virtual elimination of cross-country running, and shows the need for constant care on our part. Entrants should be over 16, and should have been vetted by the medical officer in some efficient way. I have known of three cases in which the heart was temporarily strained, and vomiting is not uncommon.

To judge from the answers received from other schools, the number and length of all runs is diminishing, and I have accumulated almost no evidence of a harmful effect on the health of school boys from the ordinary routine runs of the present day, but opinions are much more guarded on the competitive steeplechase, for which most but not all medical officers insist on a previous examination.

Swimming.—This most fascinating sport also has its danger, in that it is very fatiguing; the danger is the greater, because the fatigue is very insidious and the pleasure so great that boys will not admit it. Twenty minutes a day should be the maximal allowance (except for the early morning dip), and life-saving practice should count as a bathe. It is my experience that the sick admissions invariably go up as soon as the bathing season begins, though to a much less extent since the length and number of bathes were cut down, and the ear and catarrhal subjects were forbidden to bathe.

Unequal grouping.—As regards physique, unequal grouping is on the whole rare, though it inevitably occurs in house matches; and indeed in any game of football the strongest player must be much stronger than the weakest. There is, however, a definite danger as regards age, especially in boxing. It is surprising what a difference two years in age may make between boys of the same height, weight, and apparent strength, and I have seen the nerve of three very promising boxers broken for this sport in consequence.

Time after meals.—Twenty years ago the Medical Officers of Schools Association laid down as a result of the debate to which I have alluded, the following: "It is most important that there should be an ample interval (one hour at least) between the time of the previous meal and the beginning of exercise. There is clear evidence that the neglect of this elementary rule is responsible for a very large proportion of the ills which have been attributed to over-exertion alone." A leading article in the *British Medical Journal* in the same year said: "The only direction in which outside stimulus is perhaps required is in respect of a due interval being allowed to elapse between meals and the commencement of a game."

At that time, after six years' experience, I wondered if I had been missing such cases, and after another 20 years I am still wondering, as to my knowledge I have seen none, though I know that this rule is and has been constantly violated. If the "one hour limit" refers to runs and football, then I certainly agree, though even in the latter the small boys have played short games within 40 minutes of a meal for many years. Apart from these two, squash, fives, rackets, gym, fencing, tennis, cricket, and sprint racing have been constantly indulged in half an hour after dinner with no ill-effect, so far as I can judge.

Exercise and the Heart.

The fact is that the juvenile stomach is as elastic and long suffering as the heart, and that brings me to the most important consideration: "Is the healthy adolescent heart ever impaired by exercise?" So far as my limited experience goes, the answer is in the negative, and to quote Clifford Allbutt, "In all cases of heart disability, some infectious disease, however slight, had preceded the physical stress." Undoubtedly cases of cardiac strain and disability do occur from time to time, some of which are brought to light by some form of exercise, and the commonest causes are, *not* an attack of measles, severe influenza, diphtheria, or scarlet fever, which we can and do guard against, but the slight chill or even cold, or the milder forms of influenza, which occur so often in a big epidemic, and which to me are always a cause of great anxiety.

The difficulties are increased from the start by the fact that there is so much variation in the healthy adolescent heart, and I might add in the opinions expressed by the home doctor, the school doctor, and the cardiologist, and I agree with Dr. W. Atlee when he says, that in the absence of gross lesions, easy to detect, "one symptom is worth many physical signs, and exercise tolerance tests are the most practical value." I do not mean to belittle the value of examination. Primary examination of *all* boys on entry is of course essential, and re-examination of all delicate and suspects; but it is not among them that the danger of heart strain following exercise is most likely to develop. Regular re-examination of the whole school, advocated by many, would not, in my opinion, solve the difficulty. To examine 500 boys from the cardiac point of view, allowing 10 minutes a boy, would take 84 hours, and allowing 2 hours a day, 42 days. Much can happen in 6 weeks.

My own system, after any boy has been sick, is to leave off all exercise for three days, and then order gentle exercise for another three days or a week. This is gradually increased, football and runs being further curtailed, according to the results of my examination.

Exceptional Cases.

There are two types of boys who need a passing reference. One, the pre-puberty endocrine defective, generally of the obese variety, and often overgrown, who is capable of very little, till after puberty; and next the albuminurics. So long as a watchful eye is kept on the urine and general condition of the latter they may be allowed full exercise. Early in my career I remember two cases, whose urine contained albumin in large quantities, and whose athletic careers and characters suffered considerably from drastic efforts to stop the albuminuric leakage.

The boy who is debarred from all games is a great rarity, but many are partially barred, the one game that counts amongst them being football. Are there any bad effects as a result? Amongst the schools I consulted, five medical officers consider that bad moral effects must result, though no direct evidence has been produced, except in one instance. All the rest agree that it is very desirable that the energies of such boys should be directed into other channels.

The opinion is by no means uncommon amongst house masters, whose judgment cannot be dismissed lightly, that immorality is to be feared among this type. In my own opinion, the question of immorality depends almost entirely on the standard and tone of the school or house, but there is a definite tendency for such boys to become loafers, unless those in charge take the trouble to find some more or less congenial substitute—e.g., photography, engineering, carpentry, linesman, goal at soccer ("the haven of the tired heart"), golf, squash, fives, tennis, fencing, gym (the dangers of which have been much exaggerated), or the short go-as-you-please run, which is a glorified walk.

Athletics and Intellect.

Though not directly connected with the subject, it is worth while recording the relationship between these two. An analysis of 4500 boys who have passed through my hands shows that 39 per cent. of scholars gained school athletic distinctions, while 18·8 per cent. of the rest of the school did so. Of the scholars, those who only got junior scholarships on entry, and gained no further distinction, only produced 7·7 per cent. of athletic successes.

Athletic Sports.

These have undoubtedly become much more popular in post-war years. Every boy must enter for at least one event, and more than half the school do take part, and the heats are spread over three or more weeks. Unfortunately they seem to be associated generally with east winds, rain, or snow, and the risk of catching chills is a real one, and for purely medical reasons I should much prefer them to be held at the beginning of the summer term. Coaching and organisation has improved, and care is taken that the longer races are run on different days. Relay races were introduced here as far back as 1905. No boy should be allowed to compete out of his own class, a not uncommon happening, especially in the relay team races. It would be a good thing to limit the number of prizes that any one competitor might take.

Conclusions.

My conclusions, for what they are worth, are that games and sports in the bigger schools are on the whole very well managed and supervised, and that there is surprisingly little evidence of damage resulting At the same time, constant care is needed on the part of the medical officer and others to see that youthful enthusiasm does not lead to undue excess, and it is in the most healthy and vigorous type of school and boy that such excess is likely to occur. The truly healthy boy rarely, if ever, suffers any real harm, though he may overdo it at times. The real risk lies in boys playing games or running after some minor illness, generally slight influenza, and in times of epidemics it is impossible to be sure that no unfit boy takes part. Re-examination will not necessarily be a safeguard, as in so many cases, symptoms precede signs. In addition, if it is to be genuine, and not mere eyewash, the time involved makes such a method very difficult.

I think that routine runs of all sorts have diminished largely both in frequency and length the last 20 years, and in this respect the pendulum has swung too far. Properly graduated, they are entirely free from danger. The competitive steeplechase is, however, a potential danger, and needs close supervision, especially where ordinary cross-country runs have died out. The occasional non-compulsory changing day is of great value.

PATHOLOGY OF COLIFORM INFECTION OF THE URINARY TRACT.*

BY KENNETH M. WALKER, O.B.E., F.R.C.S. ENG.,
HON. SURGEON IN CHARGE OF THE GENITO-URINARY DEPARTMENT, ROYAL NORTHERN HOSPITAL; SURGEON TO ST. PAUL'S HOSPITAL.

IN my brief survey of the pathology of colon bacillus infections I intend to confine my attention rigidly to those cases in which no gross lesion of the urinary tract can be found. To include cases of long-standing urinary obstruction associated with such secondary changes as dilatation of the ureters, incompetence of the uretero-vesical valves, and hydronephrosis would be to complicate the subject to such a degree that not one but several evenings would be necessary for its discussion. The questions, therefore, to which I shall attempt to find an answer are these: (1) By what route do organisms reach the urinary tract in the ordinary uncomplicated case of coliform infection? (2) What are the causes that predispose a patient to infection?

The Route of Infection.

Two possible paths have here to be considered, the lymphatic and the vascular. Direct infection of the kidneys from the lower reaches of the urinary tract through the column of urine in the ureters need not be considered. Indeed it is doubtful whether this occurs even in the presence of obstructed and dilated ureters with bladder reflux and incompetent uretero-vesical valves.

It is probable that I owe the honour of opening the pathological side of this discussion to-night to the work I did some years ago on the spread of infection in the urinary tract through the lymphatics. Nevertheless I want to make it clear from the start that although I am convinced that ascending infection by the peri-ureteral lymphatics explains some of the cases of coliform infection we meet with, I believe that in the type of case to which I confine my remarks to-night the infection is more often descending than ascending.

---

* One of the opening papers at a meeting of the Medical Society of London on March 24th.

However, the less common ascending infections will be considered first.

The Ascending Route.—The fact that infection may spread from the lower urinary passages to the kidney by way of the peri-ureteral chain of lymphatics has, in my opinion, been amply proved by the experimental work of Steinck, Stewart, Eisendrath and Schultz, Paladino Blandini, Thiele and Embleton, Nelson and myself. It would be superfluous to discuss the experiments on which the proof rests, for it seems to me that the point at issue is not whether organisms may spread in such a manner but rather whether this mode of infection through the peri-ureteral lymphatic is at all frequent. My own impression is that it is not.

Some of the arguments that were formerly advanced in favour of infections of the urinary tract being ascending rather than descending are certainly fallacious. The fact that many patients complain of frequent and painful micturition before they show clinical signs of renal infection is no proof that their trouble has started in the bladder. Frequency may be a symptom of an infection that is confined to the kidney, and the order in which symptoms are noted by the patient does not provide a reliable indication of the direction in which the infection has spread. As Frank Kidd has pointed out repeated cystoscopies examinations and ureteric catheterisations will show that in many of the cases that clinically appear to be examples of cystitis followed by pyelitis the invasion has in reality taken the opposite direction. In other words, the more exact our methods of investigating the patient the more commonly do we find a descending rather than an ascending infection. Nevertheless ascending infections undoubtedly occur. A striking example of this was provided for me by a medical man who consulted me in a state of alarm because he had suddenly developed a slight urethral discharge. I found that his urethritis was due to a pure *Bacillus coli* infection. At the time of examination he had no symptoms or signs pointing to trouble elsewhere than in his urethra, but within 48 hours he had developed a typical attack of generalised infection with renal pain and tenderness, dysuria, frequency, fever, and rigors.

An argument that has frequently been advanced in favour of ascending infections, and against the theory that the kidney is first attacked through the blood stream is the fact that the blood, in cases of coliform infection, is sterile. This argument cannot be dismissed as unimportant, and the suggestion that in all probability the passage of organisms from the primary focus into the blood stream is an intermittent phenomenon and that if repeated cultures were to be made positive results would more often be obtained, does not altogether explain it. It must, however, be remembered that as a general rule organisms in the blood stream are carried by the polymorphonuclear leucocytes and do not exist free in the plasma. The chance of finding them is, therefore, increased by any process that separates off the corpuscles from the plasma. Unfortunately, however, in breaking down the leucocytes may liberate bacteriolysins which destroy the organisms and render ineffective the efforts of the bacteriologist to demonstrate their presence. It is this phenomenon that is probably to a great extent responsible for our negative results.

Unfortunately at the present moment we possess no data on which to base a decision as to the relative frequency of the ascending and descending routes in coliform infections. More observations are necessary before we are justified in arriving at any conclusion, and for this reason we must avoid the temptation to settle the matter by armchair speculations.

Predisposing Causes of Infection.

So far we have considered only the infective agent and the path by which it reaches the urinary system. It must, however, be remembered that the arrival of organisms in the kidney is not enough to produce a pyelitis or pyelonephritis. Experimentally it has been shown that coliform bacilli may be injected into a vein in large numbers without any renal lesion being produced. In order that a pyelonephritis may occur the soil must be prepared. Both experimentally and clinically it has been demonstrated that obstruction to a ureter is an effective preparation, and Dr. Elizabeth Lepper has proved that complete obstruction for so short a period as a quarter of an hour is sufficient to render the kidney vulnerable. She suggests that the mechanism of this is a rise in pressure of the distended renal veins causing venous congestion and hæmorrhage into the kidney substance. In some of our clinical cases a transient and partial obstruction of the ureter may actually be the predisposing cause to the affection of the kidney, but it is difficult to believe that this is common; and we are forced to search for other factors. Our patients find for themselves a plausible explanation in "chills" and "trauma," and although we are naturally cautious in accepting these theories, it is possible that even a mild disturbance of circulation in the kidney may be sufficient to render it susceptible to the action of hostile germs. Moreover, since Helmholtz has shown that certain strains of *B. coli* show a selective affinity for the kidney, it has become less difficult to imagine that in a patient whose general resistance is low a trifling departure from the normal may be sufficient to precipitate a pyelonephritis once these germs have reached the renal tissues.

The Source of Infection.

Clinicians and experimentalists agree that the common source of infection is the bowel. This receives strong clinical support from the fact that the invasion of the urinary tract is commonly preceded by a history of some bowel upset either in the shape of an attack of diarrhœa or of an aggravation of a habitual constipation. Two other observations, for which I am indebted to Dr. D. Embleton, point in the same direction. The first of these is Dr. Embleton's observation that if different dilutions be made of the infected urine and cultured anaerobically a *Streptococcus fæcalis* is often found in addition to the more abundant and more luxuriously growing coliform bacillus. Whether this accords with the experience of any other bacteriologist I do not know.

The second observation is that if a patient who is convalescing from an attack of coliform bacilluria be given a dose of cascara, there is an immediate increase of organisms in the urine. The irritant action of the cascara on the intestinal wall is so invariably followed by a bacilluria that this purgative may be used as a provocative agent in deciding whether a patient is cured or not of his urinary infection. From this we may deduce that irritation of the bowel wall is an important factor in the production of a coliform infection of the urinary tract. That this is so was impressed on me strongly by two instances in which the injection of an anæsthetic into the large bowel in too strong a concentration was immediately followed by a coliform bacilluria. The first was provided by a rabbit in the anæsthetising of which I had employed an over-concentrated rectal injection of urethrane, the second by a patient of Dr. J. J. Clarke's who had received by the rectum a dose of paraldehyde prior to a gynæcological operation. In both instances the colitis produced by the rectal injection was followed by a severe infection of the urinary tract. Histological examination suggested that in the case of the rabbit the colon bacillus had invaded the bladder directly from the rectum.

Now although these two cases show that inflammation of the wall of the bowel permits of the emigration of leucocytes charged with coliform bacilli, they do not give any indication of the path along which these carriers of infection travel in order to reach the urinary tract. Three routes are open to them. They may pass straight into the bloodvessels of the mesentery, they may invade its lymphatics and reach the blood stream indirectly through the thoracic duct, or finally they may reach the kidney through an all lymphatic route by branching off along the large lymphatic trunk that joins the receptaculum chyli from the renal area. That organisms may travel along lymphatic vessels in an opposite direction to that normally taken by the lymph flow has been repeatedly indicated. I am convinced, therefore, that although the first two modes of infection are the more probable the third must still be considered as possible.

Morbid Anatomy.

Whilst we must confess that clinically speaking we possess no precise knowledge of the path along which infection spreads to the kidney, as morbid anatomists fortunately we find ourselves on firmer ground. The work of Helmholtz at the Mayo Clinic, and of Nelson at St. Bartholomew's Hospital, has to my mind clearly shown that lesions of the kidney produced in rabbits by the intravenous injection of organisms tend to localise themselves in the kidney substance and in the papilla, and adjacent lining of the renal pelvis, and that ascending lesions produced by bladder inoculation tend to affect the parietal wall of the renal pelvis. Post-mortem findings support the view that what is true of infection of the kidney produced experimentally in rabbits is also true of renal infection occurring in human beings. In the fulminating case of coliform infection described by Brewer and almost certainly due to a blood invasion, the septic areas were in the kidney substance, whilst in pyelitis associated with lesions of the lower urinary tract the lateral walls of the pelvis are mainly affected.

There emerges from animal experimentation yet another fact that may be applied to infections in human beings. It has been clearly demonstrated that whilst dyes and organisms are rapidly taken up by the lymphatics of the posterior urethra little or no absorption occurs when these are injected straight into the bladder. This, of course, is equally true of such drugs as cocaine, a patient being able to tolerate in the bladder a dose which were it injected into the posterior urethra would give rise to grave signs of toxæmia. From this it would appear that an ascending infection of the kidney via the lymphatics is more likely to follow a posterior urethritis than a cystitis. It is this rapid absorption of organisms from the urethra that probably accounts for the phenomenon of catheter fever, and also for the rarity of ascending infections in cases of cystitis not associated with obstructions. It also explains the coliform infections that not infrequently follow the consummation of marriage in females. Finally it helps us to understand why a residual focus in the prostate so often is the cause of relapse in the male.

There is yet another type of case of coliform infection that may be due to an invasion of the kidney through the lymphatics—namely, that which so commonly occurs as a sequel to gynæcological operations and even to labour. The close connexion between the lymphatics of the female genitalia and those of the ureter render the kidney particularly liable to invasions from this angle. But I have already published a paper on this subject in THE LANCET of 1922, and will not go into it further at the present moment. All that need be said is that although it is probable that coliform infections of the kidney are in the main blood borne, those following operations on the pelvic organs and those preceded by a posterior urethritis are more likely to be due to a spread via the lymphatics.

Conclusions.

In attempting, therefore, to find an answer to the two questions put at the beginning of this paper, the following tentative conclusions have been reached:—

1. That the kidney may be invaded in uncomplicated cases of *B. coli* infection either by the blood stream or by the lymphatics.

2. That in the majority of cases the infection is descending, but that when it occurs as a sequel to a pelvic operation or to a urethritis the invasion of the kidney is ascending and through the lymphatics. In a few exceptional cases direct invasion of the bladder from the rectum may also occur.

3. That in the absence of obstruction a lymphatic invasion of the kidney is more likely to follow a urethritis than a cystitis.

4. That the presence of the organism in the kidney is only one of the several factors that must be considered if we are to arrive at a full comprehension of the ætiology of the disease.

NOTE ON A

WATER-SOLUBLE ACTIVE PRINCIPLE

ISOLATED FROM THE MAMMALIAN TESTIS AND URINE, AND ITS RELATION TO ŒSTRIN.

BY E. C. DODDS, M.V.O., PH.D., B.SC., M.D. LOND.,
COURTAULD PROFESSOR OF BIOCHEMISTRY, MIDDLESEX HOSPITAL;
A. W. GREENWOOD, PH.D.,
LECTURER IN GENETICS, UNIVERSITY OF EDINBURGH;
AND
E. J. GALLIMORE, B.SC. LOND.,
ASSISTANT IN BIOCHEMISTRY.

(From the Courtauld Institute of Biochemistry, Middlesex Hospital, and the Animal Breeding Research Department, University of Edinburgh.)

IN a series of recent publications, workers in the University of Chicago (Moore and McGee, 1928; McGee, Juhn, and Domm, 1928; Gallagher, 1928, &c.[1]) have shown that certain extracts of the mammalian testis are capable of causing heterogonic growth of the head furnishings (combs and wattles) in castrated fowls. Similar results have been reported by Funk, Harrow, and Lejwa[2] (1930). The active extracts have mainly been prepared by the treatment of the tissue with volatile solvents, and an oily residue has resulted.

These observations have been confirmed by us, and through a study of the properties of the active principle it has been possible to evolve a method, which is described in this preliminary note, whereby it can be obtained in a water-soluble form.

Method of Standardisation.

All the birds used for this investigation were hatched in 1928 or 1929, and were castrated at ages varying from 3 to 78 days, and at the time of injection were from 20 to 58 weeks old. Measurements of comb size were taken periodically during the development of the birds, and for some time previous to these experiments they were made at fortnightly intervals. In the individuals used for the purposes of the present tests, the combs had either been stable for some months previous to the first injection or had increased in size at a rate not greater than that which occurs in the normal immature capon. Furthermore, in none of the capons chosen were the combs more than 5 cm. in length, since it is probable that any comb larger than this, even though stable, indicated the presence of a small testis fragment which might have complicating effects on the issue of the experiment.

With regard to the criterion of activity, it was decided to regard as active an extract causing an immediate, sharp increase in the comb length of such a magnitude as to throw the curve abruptly away from the predetermined normal. Also, this sudden increase had to be followed by a definite decrease in the comb length within a short period of terminating the injections.

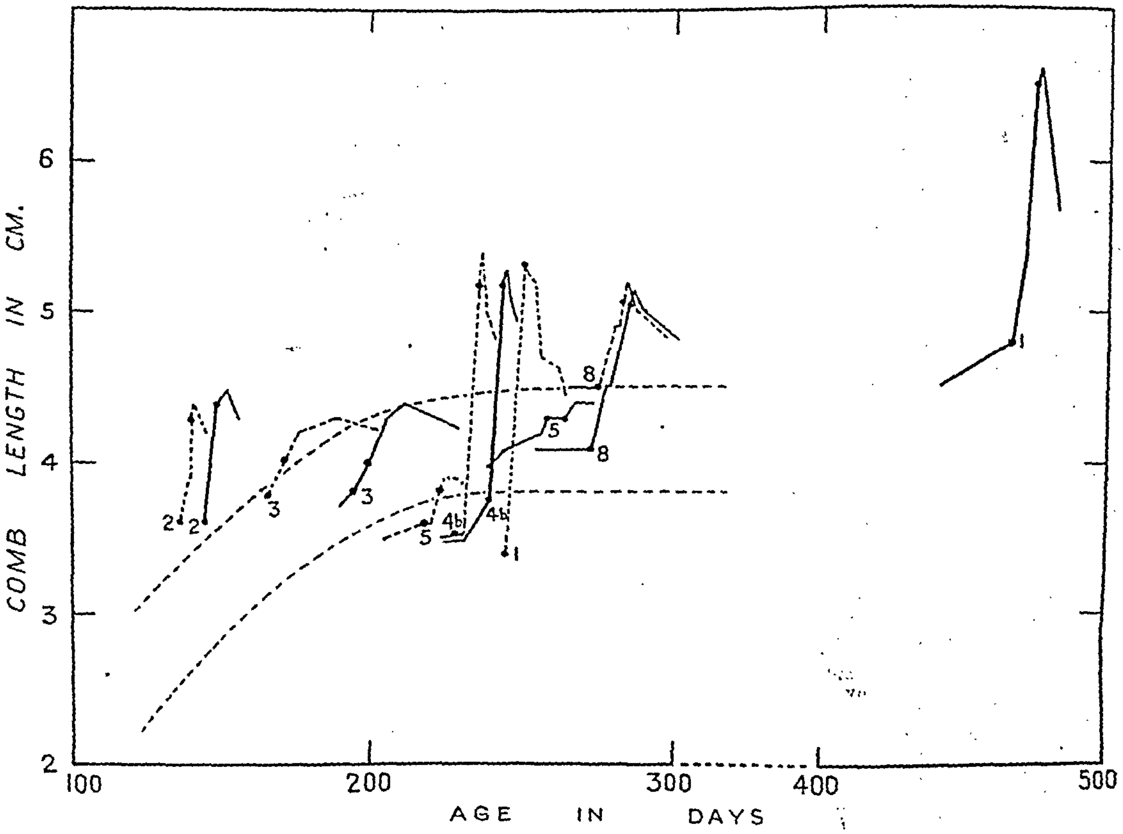

Chart showing effect of mammalian testicular extract on the combs of castrated fowls.

The growth curves for a number of normal capons for a period of from 190–300 days after hatching was found to fall within fairly narrow limits; their limit of variation is indicated in the figure by the area between the smooth curves. Though not all of the birds used in the present experiments had combs which fell between the actual limits of variation for their respective ages, yet their initial comb sizes did not deviate from the normal groups sufficiently to suggest that they were abnormal.

In order to test the potency of the various extractions, two birds were used for each product and the injections were given daily over periods varying from 5 to 12 days. The alterations in the comb length of the injected birds is shown graphically in the figure, the two dots on each curve representing the days on which the initial and final injections respectively were given. It will be seen that in the case of some of the extracts (Nos. 1, 2, 4b, and 8) a rapid growth of the comb resulted to a point much beyond that characteristic for the normal capon of similar age, and that when administration of the substance ceased this was followed by a rapid decrease in comb size. Extracts Nos. 3 and 5 were considered to be inactive.

At the present stage of the investigations it is felt that any quantitative interpretation of the results is unwarranted, and the results recorded here are intended to convey a purely qualitative idea of the activity of the various preparations.

Preparation.

The essential steps in the development of the process for isolating the growth-promoting factor are given in the following scheme of experiments. The starting-point in each case was a benzene extract prepared in accordance with the publications of the workers referred to in the beginning of this paper. The standardisation of this material is shown in curve 1 of the figure.

Crude benzene extract (1) [Active]
dissolved in ether—acetone added

Filtrate freed from solvent (2) [Active]
Precipitate [Inactive]

Saponified with sodium ethoxide (5) [Inactive]
dissolved in 50 per cent. alcohol.

Saponified with $Ba(OH)_2$
Ba removed with H_2SO_4
Centrifuged

Supernatant (4b) [Active]
Precipitate [Inactive]

If filtration be adopted in place of centrifugation for the removal of the barium sulphate in the above scheme the potency is lost (3). The final product by the above type of method consists of a water-bright solution containing some 2 mg. per c.cm. of solid contents. This is non-toxic and non-irritant when injected into animals and, as already noted, contains activity. The potency can be extracted from this water-bright solution by ether, and if slow absorption is required it can be dissolved in sesame oil.

From the above experiments the following process was reached by the direct application of barium hydroxide to the minced testes.

Process.

The final method adopted is in every way similar to that published by Allan, Dickens, Dodds, and Howitt [3] for the preparation of œstrin from placenta. The details of the process may be obtained from that publication, but the following gives a brief outline of the method.

8 kg. of minced testes are mixed with 8 litres of water and 1·6 kg. of crystalline barium hydroxide. The mixture is boiled for two hours in a steam-heated pan with a reflux condenser. The resulting mass is at once filtered through jean and is evaporated down to about 5 litres, cooled and extracted with 2 litres of butyl alcohol for half an hour in a shaking apparatus. After separation of the supernatant alcohol the solution is re-extracted with two further quantities of 1 litre of butyl alcohol for half hour each. The butyl alcohol is then removed by distillation in vacuo below 70° C., and the residue is dissolved in 600 c.cm. of hot water and, after filtration, the filtrate, residue and filter paper are extracted with three successive quantities of 600 c.cm. of ether. The ether extract is washed always with 600 c.cm. of water and the ether is then removed on the steam bath and the resulting solution is evaporated to dryness in vacuo. The remaining traces of butyl alcohol are removed by the addition of a little water and distillation. The residue is found to be highly active in producing comb growth (No. 8 in figure).

Alternatively, a purer preparation may be obtained by taking the residue from the ether by evaporation and dissolving it in about 10 c.cm. of absolute alcohol, followed by the addition of 80 c.cm. of water. The resulting suspension is boiled and 10 c.cm. of a 10 per cent. boiling solution of crystalline barium hydroxide is added. The mixture is then boiled for one hour under a reflux condenser, and after cooling a theoretical quantity of H_2SO_4 is added to precipitate the barium. The resulting mass is centrifuged and the precipitate extracted with absolute alcohol and again treated with barium hydroxide in a similar manner. The clear, pale yellow supernatant fluid is evaporated down to remove the alcohol to a convenient volume. The resulting solution is clear, almost colourless, free from alcohol, and contains the active principle (8).

The Resulting Extract.

The activity may be extracted from an alkaline aqueous solution by means of ether, and after removal of the ether the residue may be dissolved in sesame oil. Experiments are in progress to determine the relationship of the potency between aqueous solutions and oil solutions of the active principle, in a similar manner to those recorded with regard to œstrin (Allan, Dickens, and Dodds [4]).

This process may be applied to the urine of men from which the substance can be prepared. The urine is evaporated almost to dryness and the residue boiled with benzene for one hour. The benzene is distilled off in vacuo, the last traces being removed by the addition of a small amount of alcohol and then redistillation. The resulting oil may be emulsified in water and sesame oil for injection, or may be treated by the baryta process if water-soluble material be desired.

Comments.

The properties of the active principle bear a very striking resemblance to those of œstrin. Thus, both hormones can be extracted by the addition of volatile solvents and both will stand prolonged hydrolysis with barium hydroxide. They can both be obtained in a water-soluble form and the properties of the two solutions are identical.

This relationship becomes still more interesting in consequence of the claims of such workers as Laqueur and de Jongh,[5] Brouha and Simonnet [6] that œstrin may be obtained by extracting testes with volatile solvents. The effects of the comb growth promoting extract on ovariectomised rats is being studied, and whilst an œstrus effect has been observed with one preparation it is as yet too early to express an opinion upon the physiological aspect of the relationship between these two hormones.

Summary.

1. A method of testing an active substance extracted from testes and urine by observing its effect on comb growth in capons is described. 2. It is shown that the active principle may be obtained in a water-soluble form, and its chemical properties are briefly reviewed. 3. Its similarity to the œstrus-producing hormone as prepared from placenta and the urine of pregnant women is noted.

CORONARY THROMBOSIS AND COMPLETE HEART-BLOCK.

WITH A NOTE ON THE FEBRILE REACTION IN CARDIAC INFARCTION.

By K. SHIRLEY SMITH, M.D., B.Sc., M.R.C.P. Lond.,

PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS; MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

Among the disorders of rhythm which may accompany cardiac infarction heart-block is frequently mentioned. While varying grades of partial block are not uncommon, complete auriculo-ventricular dissociation is a rarity. Thus in a series of 145 cases Levine and Brown [1] recorded only two instances; again Parkinson and Bedford [2] found complete heart-block only once in a series of 100 cases. Two reasons are advanced for the comparative immunity of the conducting system from the damage ensuing from coronary occlusion. First, that the interventricular septum is supplied by both the right and the left coronary arteries, and secondly that the vessels which supply the region of the auriculo-ventricular node, the bundle of His, and its two main branches are derived from the coronary arteries proximal to the usual site of obstruction.

Although the occurrence of complete heart-block is rare as a sequel of coronary thrombosis, the association of these two conditions in the converse order is still less common. The perilous state of a patient suffering from complete auriculo-ventricular dissociation and frequent Adams-Stokes attacks is sufficiently obvious; but when coronary thrombosis supervenes to add its own dangers to those already present, the condition of the patient becomes extremely grave. This sequence of events has been recently observed throughout all its phases by the writer, and will be further referred to in detail.

The ætiological significance of syphilis in the pathogenesis of heart-block has been stressed from time to time. That coronary thrombosis is essentially an acute phase superadded upon chronic arterial disease is generally accepted, and the association between heart-block and acute coronary occlusion would seem therefore to suggest that arterial degeneration is a more common factor in the production of heart-block than has hitherto been recognised. While in the instances here quoted the dissociation followed sudden restriction of the coronary blood-supply, it is likely that gradual changes in the same vessels would gradually produce the same effect, especially in elderly subjects where little or no possibility of arterial compensation exists.

Gallavardin [3] has reported his observations of two patients with complete heart-block as a result of coronary thrombosis. In the first case, block supervened five days after the onset of illness and lasted for three days at the rate of 30 per minute. In the second case sudden syncope for several seconds concluded an attack of prolonged anginal pain, and for the following four days the pulse was regular at 42 per minute. Two other cases have been described by Wearn.[4] The first patient was found to possess the new rhythm on the day following the onset of pain. The second developed a partial heart-block after a few days' illness, complete block developing subsequently. In this patient changes of rate were accompanied at first only by pauses in the pulse, but later by fainting attacks as well. Frothingham [5] records a case in which the onset of epigastric pain and collapse were related to extreme heat. On the same day an electrocardiogram demonstrated complete heart-block at 40 per minute. The rhythm gradually returned to normal and ultimate recovery followed.

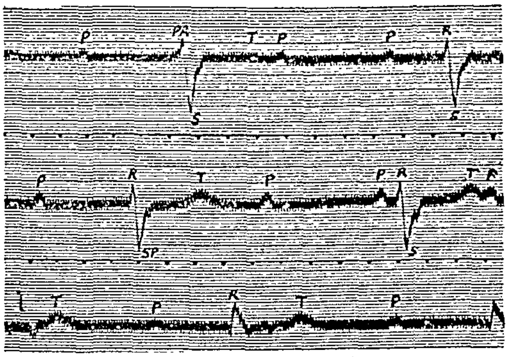
An account is given below of a patient suffering from complete heart-block with Adams-Stokes attacks, in whom coronary thrombosis supervened. Certain of the investigations made in this case seem worthy of record, in particular the charts of oral and rectal temperature. These and other aspects of the case are subsequently discussed.

Summary of Case.

The patient, a man of 59, was admitted to the Middlesex Hospital on Dec. 7th, 1929, complaining of fainting fits, breathlessness on effort, and pain in the left side of the chest.

History.—There was no significant family or personal history. In March, 1929, the patient had the first of a series of attacks in which he fell down unconscious. These seizures recurred at intervals until August when they became much more frequent, only a few days intervening between them. They were usually ushered in by dizziness, loss of consciousness for a few seconds following. Although their frequency was increasing, it was noticed that the attacks were becoming less severe. During October the patient began to experience pain in the left side of the chest and breathlessness on exertion.

FIG. 1.

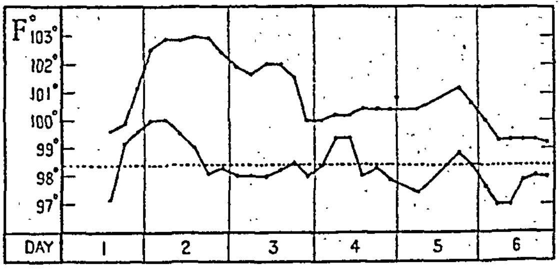


Electrocardiogram taken 20 days after the onset of coronary thrombosis in a patient previously suffering from complete heart-block. The curves show complete auriculo-ventricular dissociation with a left branch bundle block.

Examination.—The patient did not appear ill or distressed. There was no fever, nor were there any signs of congestive failure beyond a faint cyanotic tinge in the face and slight pulmonary œdema. The rhythm of the heart was regular at 30 beats per minute. The heart was not enlarged. Distant heart sounds were heard at the apex and base, but no murmurs were detected. The arteries were moderately thickened and the fundi were normal. The blood pressure was 180/75. The urine was normal. Wassermann reaction negative.

Progress.—Two days after admission the patient had eight successive slight Adams-Stokes seizures, all occurring within an hour. In these attacks there was no loss of consciousness; they were preceded by sensations of faintness, dizziness, and swaying of the body. No pulse was felt at the wrist, nor were any heart sounds heard during the five or six seconds over which each attack lasted. Although the patient was put on barium chloride, gr. ½, and subcutaneous injections of adrenalin, ♏iii., each thrice daily, two or three slight attacks occurred almost every day subsequently.

FIG. 2.



Temperature chart during the first six days after coronary thrombosis. The readings shown in the upper curve were taken in the rectum; those in the lower curve in the mouth. Note initial subnormal mouth temperature and subsequent wide disparity between oral and rectal temperatures.

Onset of coronary obstruction.—Following two days of slight dyspnœa and vague pain in the left mammary region, there was sudden onset of pain over the lower third of the sternum and epigastrium on the evening of Dec. 20th. This persisted all night and had become very severe by noon on the 21st. Examined at this time the patient was restless and rather collapsed. There was profuse sweating of the head, neck, and chest; the complexion was greyish and cyanosed, and the extremities were cool and clammy. The pulse remained slow and regular. Increasing pulmonary œdema was observed.

Two hours later fairly frequent extrasystoles were felt at the wrist. The temperature by the mouth was 97·2° F. while that in the rectum was 99·6°. Oxygen by nasal catheter was followed by some improvement in the general condition. When the patient awoke after an injection of morphia gr. ¼, the pain was very much relieved although it returned with any slight effort. A leucocyte count 40 hours after the onset of the pain showed 22,000 leucocytes per c.mm. Subsequently, frequent temperature readings were taken in the mouth and in the rectum, showing well-marked pyrexia.

Three days after the onset there were pain and tenderness and rigidity in the right upper quadrant of the abdomen. The liver was not enlarged, nor had the signs of failure increased. Frequent tests of the urine showed no albumin or sugar. During succeeding days the liability to pain on movement gradually disappeared, and fever rapidly vanished. No Adams-Stokes attacks recurred after cardiac infarction had set in.

The leucocytosis reached a maximum of 28,000 eight days after the onset of the illness; three weeks later the count had fallen to within normal limits. Three days before the beginning of the myocardial necrosis the blood pressure was 165/110. Sixteen hours after the onset of the pain, while this was still severe, the reading was 200/75, the rate being slightly increased by occasional extrasystoles. Seven days later the blood pressure reached the lowest figure recorded during the illness, 130/60. Another six weeks elapsed before the pressure had increased to 160/75.

Electrocardiograms.—In June, 1929, three months after the earliest Adams-Stokes attacks, the patient attended the National Hospital for Diseases of the Heart. An electrocardiogram taken at this time showed a normal rhythm; the T-waves were rather flattened, and there was some left ventricular preponderance.

The record shown in Fig. 1 was taken 20 days after the onset of coronary thrombosis. A normal auricular rhythm is present with a very slow independent ventricular rhythm. The form of the ventricular complexes points to a left branch bundle block. It is doubtful whether the branch bundle lesion is referable to involvement of the septum in the recent myocardial damage, or whether the combination of complete and left branch bundle block was present before acute coronary obstruction occurred.

Comments.

That the functional integrity of the conducting tissues is closely related to the adequacy of their blood-supply is demonstrated by the case described above and by others to which reference has been made. It might be expected that if permanent occlusion of one of the coronary vessels may result in permanent heart-block, transient ischæmia as occurs in angina might temporarily produce such a block. This, in fact, occurs. Gallavardin[3] has described a syncopal form of angina in which slowing of the pulse occurred during the attack, but in which this slowing could not be definitely established, as the normal rate was resumed at the end of the attack. Again, Huchard[6] has given an account of a patient who suffered from typical attacks of angina pectoris which were accompanied by vertigo and sometimes syncope. In one very severe attack the pulse slowed to 28 over a period of ten days, and later fell to 24.

Embolism of the coronary arteries has been described by Gallavardin and Dufourt,[7] who observed this unusual event in a patient of 63 who suffered from hypertension and cardiac enlargement with gallop rhythm. Severe epigastric and præcordial pain set in with progressive collapse and rapid death. During this final illness the pulse slowed to 28 and 22, and at autopsy an embolus was found in the left coronary artery at its bifurcation into circumflex and anterior descending branches. Three similar cases are cited by the same authors, the obstruction in each instance being at or very close to the bifurcation of the left coronary artery. The more proximal position of the occlusion in embolism as compared with that in thrombosis must explain the greater liability to heart-block in the former condition.

Febrile Reaction.

The febrile accompaniments of cardiac infarction are too well known to need any reiteration. The case just described illustrates these phenomena. Levine and Brown[1] have remarked that a patient during the onset of coronary thrombosis may have well-marked fever in an observation taken per rectum, while the mouth temperature is still subnormal. In the present case this difference was well shown, and four-hourly temperatures taken both orally and rectally were charted. These curves are reproduced in Fig. 2 and show a very pronounced disparity lasting over four days. While the mouth temperature was still subnormal that in the rectum was higher by 2·4° F.; within 32 hours of the beginning of the attack a difference of 2·8° F. was recorded, and when during the next 12 hours the mouth temperature fell to 98° F., the disparity was 4·8° F.

The explanation of these febrile phenomena is probably to be found in the combination of an acute inflammatory process and a state of collapse with sweating over the head, neck, and chest. The cooling of the periphery is exaggerated in the upper part of the body by heat-loss from evaporation. Conversely, within the pelvis, where heat-loss is reduced to a minimum, the febrile reaction due to acute necrosis in the myocardium is able to declare itself.

My thanks are due to Dr. C. E. Lakin for permission to use the notes and records of the case described; to Dr. G. E. S. Ward for the electrocardiographic report; to Prof. J. McIntosh for the leucocyte counts made in the Bland-Sutton Institute of Pathology; and to Dr. R. O. Moon for supplying information concerning the patient during his attendance at the National Hospital for Diseases of the Heart.

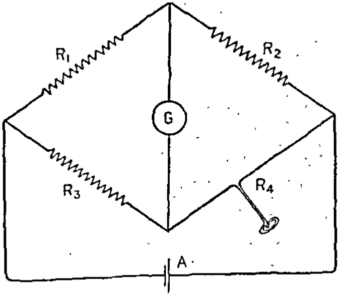
Clinical and Laboratory Notes.

A PLATINUM RESISTANCE THERMOMETER

FOR MEASURING THE TEMPERATURE OF THE SKIN.

BY F. CAMPBELL SMITH, B.SC. LOND., M.R.C.S. ENG.,
FREEDOM RESEARCH FELLOW, LONDON HOSPITAL.

I HAVE devised a method for the measurement of skin temperatures by means of the platinum resistance thermometer which, I believe, is in several respects preferable to the more usual thermo-electric method, as described by Benedict[1] and others. The method has the following advantages: (*a*) the apparatus is portable, being contained in a case measuring 9 by 9 inches by 6 inches in depth; (*b*) the thermometer is robust, and may be applied by an unskilled operator; (c) the galvanometer is direct, reading in degrees Centigrade or Fahrenheit. The essential parts of the apparatus are shown diagrammatically in the figure.



A = Two-volt dry cell. R_1, R_2, R_3 = Resistances, each of 50 ohms. R = Resistance thermometer. G = Unipivot micro-ammeter graduated in degrees.

The thermometer itself consists of a flat spiral of insulated platinum wire (No. 48 gauze) cemented to the end of an ebonite rod, and held in place by a thin film of celluloid varnish; the diameter of the disc applied to the skin is about 8 mm. With regard to the galvanometer, a micro-ammeter of the unipivot type is sufficiently sensitive. The thermometer, as will be seen, forms one arm of a Wheatstone bridge; a thermostat, therefore, is not required.

---

[1] Benedict, F. G.: Leopoldina (Amerikaband), 1927, iv., 129.

In making a measurement, it is necessary to bring the thermometer to a temperature as close as possible to the temperature of that part of the skin which is to be measured; this is conveniently done by holding the surface of the thermometer in the palm of the operator's hand for half a minute. The current to the bridge is then switched on; when the galvanometer needle has become steady, the thermometer is applied to the skin. A reading, accurate to 0·05° C., may be obtained within 3–6 seconds.

The apparatus may be obtained from Messrs. Griffin and Tatlock, Ltd., Kingsway, W.C. 2.

A CASE OF CARCINOMA OF BRONCHUS.

By L. S. T. Burrell, M.D. Camb., F.R.C.P. Lond.,

PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

A WOMAN, aged 27, had a small hæmoptysis on Oct. 17th, 1929. This was followed by a slight irritating cough but otherwise there were no symptoms and she had previously been in good health. The cough continued and radiological examination in December showed a dense opacity in the middle third of the left lung. The shadow was continuous with the hilum and had a well-defined lobular margin; it did not extend into the apex of the lung.

Artificial pneumothorax was induced for diagnostic purposes and the mass was found to be intrapulmonary. Operation was performed on Jan. 8th, 1930, by Mr. Tudor Edwards. The lung was incised and a mass the size of a walnut was found in a bronchus. The bronchial wall was much stretched and thin so that it appeared as a capsule, but the growth could be shelled away except one portion where it appeared to be growing by a pedicle. It was successfully removed and the bronchus was ligatured. On section the growth was found to be carcinoma. The patient made an uninterrupted recovery and has now left hospital.

This case is similar to two cases[1] in which small pedicled growths were removed through a bronchoscope; in both these cases, however, the tumours were fibromata and non-malignant. In the present case the growth appears to have started as a small pedicled tumour and not in the usual form of bronchial carcinoma invading the bronchial wall. It is interesting to note that a considerable portion of the shadow seen by X rays was due to collapsed lung beyond the tumour, and it should be remembered that a large X ray shadow does not of necessity mean that the growth is large or inoperable.

---

[1] THE LANCET, 1927, ii., 1180; and 1929, ii., 708.

PROGRESS OF CONTRIBUTORY SCHEMES.—Of the total income—£124,151—of the Merseyside Hospitals Council £108,253 was contributed by the Penny-in-the-Pound Scheme (227,626 members), which was more than was budgeted for from all sources. The income in 1929 was nearly double that of 1928. A contributory scheme for people of moderate means is being prepared.—Last year approximately £31,000 was raised by the Workers' Contributory Scheme in connexion with the East Suffolk and Ipswich Hospital; rather more than one-half of the money was subscribed in Ipswich and its environs. The subscription is 3*d*. per week. Sixty per cent. of the hospital's income is derived from this source.—At the second annual meeting on March 13th of the Merseyside Association of Hospital Contributors (Penny-in-the-Pound Fund), it was reported that during the year the fund raised £122,940. Of this, £92,000 was passed on to the Voluntary Hospitals and Radium Fund, £24,698 paid to poor-law and unassociated hospitals, and £3119 spent on convalescent and after-care services. It was decided that the Merseyside area should comprise districts within a radius of ten miles of Liverpool Town Hall.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society held on March 24th the chair was taken by Mr. DONALD ARMOUR, the President, and a discussion on

COLIFORM INFECTIONS OF THE GENITO-URINARY TRACT

was opened by Sir THOMAS HORDER. He excluded gross disease processes, such as infection complicating enlarged or malignant prostate, renal and vesical calculus and neoplasm, tuberculosis, stricture of the urethra, and infection following instrumental examination, but pointed out that these must be considered before any case was regarded as a primary infection. The avenue of invasion, he said, was notoriously dubious. The proof of a hæmatogenous route was slender and the sudden onset often quoted in its favour might be seen in catheter cases. Analogies with staphylococcal renal infections were dangerous, and the rare positive blood culture was not admissible as certain proof. It was always possible that the blood infection might be subsequent rather than precedent to the urinary infection. The lymphatic route was equally difficult to prove or deny. Highly suggestive facts were the proximity of the colon to the renal pelvis, the special tendency of the right kidney to infection, and its liability during pregnancy. An alternative lymphatic route was along the course of the ureter. It was unwise to conclude too hastily that the ascending route was not followed in some at least of the cases where the maximum intensity of infection was in the renal pelvis. The pelvis was the most susceptible part of the urinary tract, and even when the onset strongly suggested a pyelitic origin the bacillus might also be present in other parts of the tract. In some cases the prostate might be the tissue through which infection reached the tract, even in the absence of disease or enlargement. Some patients had severe dysuria and passed blood and pus in the initial stages with no clinical suggestion of pyelitis. It seemed certain that the prostate might be a source of reinfection. The fairly frequent association of disease in the alimentary tract with urinary infection was occasionally overstressed, but this was better than neglecting it; the alimentary defect might be a subinfection or an anatomical lesion or both. Proof of the presence of a coliform infection was very difficult if not impossible at present. The organic lesions actually found included diverticulitis, sepsis of the gall-bladder, appendicular disease—especially chronic infection accompanying mechanical disabilities—ulceration of the colon, and the grosser forms of enteroptosis. The association of constipation was almost universally accepted but very hard to prove. It was so common that many patients suffering from coliform infections of the urinary tract were bound to be constipated. The fact remained, however, that therapeutically it was useful to correct colon stasis. Some cases originated during or just after a period of looseness, but these should probably be interpreted as instances of bowel infection complicated by urinary infection. It was probably wisest to attach significance to the bowel subinfection rather than to the constipation. Important minor anatomical defects included piles and anal fissure.

The disease had many vagaries; it occurred at all ages, and varied in intensity from a mild pyrexia to stranguary with the passage of blood and pus. It might show itself as hæmaturia alone, or a complication like epididymitis might be the first thing that brought the patient under observation, or his condition might be diagnosed for years as "recurring influenza." Relapses were very common indeed. He visualised every transition in intensity from bacilluria, causing pyrexia and general toxic symptoms, and the most severe infection, leading to pyelonephritis or extensive ulceration of the bladder. Most cases fell between these two extremes.

Treatment.

Here, as elsewhere, the fullest diagnosis must be made. The infecting agent must be known, but very often an organism that was bacteriologically "pathogenic" caused milder symptoms than one which was classified as *Bacillus coli communis*. The less readily the case yielded to general treatment the more cautious must the practitioner be in accepting it as a primary case, but it was difficult to decide what investigations of the urinary tract should be made. Sir Thomas Horder did not consider that a full routine examination in all cases was in the patient's best interests, and deferred cystoscopic examination until after a complete general treatment had been tried in patients who offered no clinical or radiological evidence of renal enlargement or gross disorder of the ureter and bladder.

X rays were useful in reviewing the alimentary tract. The good results of adjusting a defect in the bowel was sometimes very striking. Often enough, however, the most careful search failed to show any recognisable lesion. As he regarded the troubles of enteroptosis as due to circulatory and neuromuscular defects he did not advise colon-pexy, but introduced into the scheme of treatment such measures as corsets, massage, breathing exercises, and the semi-Trendelenburg position. That constipation should be dealt with effectively was agreed, though methods varied. The denudation of the mucous membrane, which was the physical mechanism by which aperients acted, could only be expected to encourage the auto-infection by which urinary infection was supposed to take place. "Changing the intestinal flora" sounded attractive, but how to accomplish it and the results of doing so were still unknown. Diet played an important part in the treatment of some at least of the cases; the protein should be reduced considerably, and game, eggs, and raw milk forbidden. Whey, butter-milk, cream, and even junket could be allowed; it seemed to be the casein residue that was harmful. This was admittedly empirical, but seemed to have good results.

A good number of these patients were neurasthenic; the corresponding condition in the child was perhaps precocity, often in an only and spoilt child. The adult frequently had a low blood pressure. The disease was much more common in private than in hospital practice and in professional than in business life, and was common in doctors. It might possibly be connected with irregular habits, hurried meals, lack of adequate rest, or exposure to infection; at any rate to combat these factors was part of the treatment. Of chemical remedies two stood out prominently: the simple alkalis and the hexamine group, the former in the pyrexial cases and the latter in subacute and post-febrile stages and in chronic cases. So successful was alkalisation that its failure should throw doubt on the diagnosis, and suggest the presence of some other factor. To a lesser extent the same was true of hexamine. To ensure the acidity of the urine, acid sodium phosphate was prescribed concurrently but separately—e.g., after food when the hexamine was given before food. In intractable cases it was a good thing to vary the form of the hexamine, as sometimes one kind seemed to work better than another. Intravenous agents such as mercurochrome had been tried, but without striking results. The method should, however, be used in those rare cases in which anuria or vomiting was present. Antigen therapy had not lived up to its original promise, but was worth trying in difficult cases. Some immunologists gave large initial doses, aiming at a reaction, but Sir Thomas Horder aimed at an amount just short of a reactive dose, believing the process to be an educational rather than a disciplinary one. Lavage was notoriously good for inflammation localised to the bladder, but irrigation of the renal pelvis was irrational and had not proved satisfactory. Direct surgical interference with the kidney had now been abandoned.

Mr. KENNETH WALKER then read the paper which appears on p. 681.

Experiments on Animals.

Dr. H. P. NELSON claimed that the pathological picture produced in the kidneys by an ascending infection differed essentially from that produced by a hæmatogenous infection, and described experiments that he had performed on rabbits. When he introduced about two thousand million colon bacilli into the bladder, after this had been prepared by pure turpentine, the blood infections were so transient, while the kidneys showed gross abscesses, that he was convinced that the blood infection was the result and not the cause of the spread to the upper urinary tract. The blood remained sterile in animals which had no kidney lesion, and he thought that the kidney and blood alike were infected through the ureteral lymphatics. Trauma was the deciding factor—apart from virulence of the organism and resistance of the host—in deciding whether an animal got its lymphatics infected or not. He suggested that the organisms entered the lymphatics through the urethral mucous membrane and not through the bladder. Rabbits which had received intravenous injections of colon bacilli might have their blood swarming with organisms and yet none could be found in the urine. Pyelitis was predominately a disease of the female rather than the male infant. The female urethra was buried at the bottom of a moist cleft and the napkin of the baby suffering from diarrhœa became saturated with virulent colon bacilli. It had been shown experimentally that bacilli from the urethra reached the kidney in an hour and a quarter, and it seemed unnecessary to blame the infant's colon. The argument against ascending infections was the absence of cystitis, but urethritis had not been excluded. The passage of organisms from the colon to the kidney had not been supported by experimental work; the kidney might be surrounded by a virulent abscess without getting infected. When the organisms were introduced into the bladder the lesions at post-mortem were cystitis of varying severity and abscess on the parietal wall of the renal pelvis, with hypertrophy and hyperplasia of the neighbouring mucosa. When the organisms were injected intravenously the lesions always consisted of inflammatory streaks in the papilla, which proved microscopically to consist of peritubular collections of polymorphonuclear leucocytes.

Discussion.

Mr. J. P. LOCKHART-MUMMERY agreed with Sir Thomas Horder that the most usual route, generally speaking, was the mucous membrane of the urethra, the reason probably being the unfortunate proximity of the urethral opening to the anus. He believed that most cases were due to primary infection from the large bowel. One of the conditions most frequently incriminated was hæmorrhoids; he thought that infection could only be conveyed from piles by the blood stream or the lymphatics if the surface were broken, and that it was never propagated by uncomplicated piles. A very common source was a fissure or fistula, which was often unsuspected and the treatment of which would generally cure the condition. He had never met with a case of diverticulitis unaccompanied by a marked coliform infection of the urinary tract; the route was difficult to determine but was, he thought, usually the lymphatics of the ureter.

Dr. T. JOEKES pleaded for a more extended trial of treatment by the bacteriophage of d'Herelle. One of the chief difficulties was the very narrow specificity of this series of organisms. He described his methods of cultivation in broth, the only successful medium. If bacteriophage was already present in the stools, as shown by its effect on the actual infective organism, a culture was made from the second filtrate and passaged very many times until it became virulent. If left too long in contact with the organism, tolerance was established. It was essential that the urine be made alkaline for this treatment. Cases of seven or eight years' standing had been cured.

Sir **THOMAS HORDER**, in reply, regretted the commercialisation of the bacteriophage in France, and welcomed the attempt of a British pathologist to explore its possibilities. He mentioned Besredka's method of applying an antigen to the intestinal mucous membrane for dysenteric conditions; if only a part of what the French workers had claimed for it was true it should be worth trying on the urinary tract, particularly in vesical infections.

Mr. **WALKER** also replied.

HUNTERIAN SOCIETY.

ATHLETICS IN SCHOOLS.

AT a meeting of this Society held on March 24th, with Dr. **ERNEST YOUNG**, the President, in the chair, Dr. **L. R. LEMPRIERE** opened a discussion on Athletics in Schools; his paper is published in full on p. 679.

Dr. **A. I. SIMEY**, whose experience was based on nearly twenty-two years' work as school medical officer at Rugby, did not intend his remarks to apply to Rugby in particular. Boys at public schools, between the ages of 13½ and 18½, were passing through the critical stage of adolescence. The range of games played was a wide one, especially during the winter terms, and to these were added the exercise demanded by the officers training corps and physical training classes. Inter-school matches and competition between the various houses threw a considerable nervous strain on the boys and added to the difficulties of the doctor. The aim should be to preserve fitness of mind as well as body. Schools should be judged neither on the number of blues and internationals they could produce, nor on the number of their university scholarships; education was not measured by either of these standards. A healthy body did not necessarily imply an athletic body. The word "athlete" was derived from the Greek word meaning "a contest"; the corresponding adjective had the meaning "struggling, unhappy, wretched, and miserable." Our present system of school games was over-organised and pushed too far. Boys were taught to play everything in the correct manner, so that they undertook athletics for athletics sake rather than for the sake of body and mind. Spontaneity in recreation was essential; the most graceful games that could be observed were the unpremeditated acts of young cats and dogs rather than the behaviour of trained and bridled horses. The fact that the standard of football had risen in a school did not necessarily mean that it would produce better citizens. At present there was a perpetual egging on of boys to perform athletic feats in hours which might be devoted to some other form of recreation. When a boy was heard to express pleasure at being "excused games" it was a sign that he was overdriven. Most boys were delighted when a "non-compulsory changing day" was established; those interested in the arts or music had an opportunity to pursue their taste, and it was important that their development in these branches should not suffer. From the establishment of the Greek games in 776 B.C. to their abolition by Theodosius in A.D. 392, there was no evidence that the athletes underwent any prolonged training before the games.

Dr. **HELEN BOYLE** said that she also had sought the derivation of "athlete" but evidently in a different book, since the references to misery were omitted. Having its origin in "contention" athleticism now referred to all games. She had noted with interest that Greek boxers developed their muscles by delving in the earth, and regretted that this use for boxers had now lapsed. In England athletic competitions were begun at Sandhurst in 1812; in 1840 Rugby, Eton, and Harrow followed suit, and the first contest between Oxford and Cambridge took place in 1864. It was doubtful whether we had improved markedly as a race since the introduction of these sports. Athletics were essential to our present school system, but was it certain that the present system was the most desirable one? It was not for nothing that "mens sana" came first in the tag; it should not be forgotten that it was possible to have a healthy body with an unhealthy mind, nor that great mental capacity can coexist with considerable bodily infirmity. Every generation differed from the preceding one, and continual reconstruction was necessary to fit education to new needs. Civilisation was the art of living together, and education should be as fluid as life. Athletics were valuable in that they pictured the conflicts coming later in life. A famous head-mistress once said: "If you can come out for a duck and not look a fool you have done something." Games should teach a child how to be a fool and not look it. They also introduced unselfishness, with pleasant associations of the herd spirit and the approval of the herd. But at present there was not room for every type of personality to develop. A dislike for games was not a sign of depravity; they might sometimes hamper a child who was better free. The main use of a healthy body was the capacity of its owner to work, and one of the severest tests of health was work in confined ill-ventilated quarters without opportunities for exercise. The too eager cult of games led to a belief on the part of the child that anything useful or productive was not recreation—a poor psychological start in life. We must ask ourselves whether the present system produced the best citizens.

Administration of School Games.

Mr. **H. M. ABRAHAMS** said that the difficulty of the present system lay not with the games but with their administration. Physical interference in games was the fault of the masters, and the danger to the athletic boy was not of an enlarged heart but an enlarged head. Too much emphasis was laid on cups and trophies and too little on the effort which should be put into games irrespective of results. Boys should be taught the rudimentary principles of sports at school, so that they might develop later. The stop-watch and tape-measure should be abolished, and the position of games should not be out of proportion to their importance. Competition should be rare, and as many persons possible should be involved in all contests. Not less, but more attention was needed, so that all might learn the proper use of limbs and the rudiments of style.

Dr. **ADOLPHE ABRAHAMS** referred to the commonness of albuminuria in athletic subjects during adolescence and its rareness in the seasoned athlete. He went on to say that athletic schoolboys seldom materialised into famous athletes later; this was usually put down to "strained heart," but in reality no such condition existed. The schoolboy's heart was as elastic as his stomach. The period of deterioration or stagnation could be weathered if the boy were sufficiently determined, but comparatively few cared to make the effort. Compulsory games were an invention of the devil and should be abolished. Running was the normal form of exercise, and boys should be taught to run; after that they could play what games they pleased with a fair chance of success.

Effects of Training.

Group-Captain **MARTIN FLACK** said that he had examined many hundreds of boys between the ages of 17½ and 18½ for the Royal Air Force. Public school boys made good pilots because they had led an open-air life, they had learned to play the game, and they had never done sufficient work to ruin their eyesight. The value of athletics in schools was to overcome the disadvantages of the upright posture, which placed the main supply of our blood below the pump. Games should tend to strengthen the abdominal muscles, and to assist the flow of blood back to the heart, and therefore those games were most valuable which introduced the greatest amount of contortional ability, provided always that the duration of the exertion was not too long. Respiration should involve the full use of the lower ribs, not of the upper chest merely. The proper results of training could be exemplified by an individual case:—

> A recruit at his first examination had a pulse rate of 84; on rising slowly to his feet over a period of three seconds, the rate went up to 96 and returned quickly to 84; after standing five times on a chair it rose to 180; and fell to normal in 35 seconds. After two months' training the pulse rate was 72; on standing it rose to 84 and fell quickly to 72; on exercise it went up to 96 and returned to normal in 15 seconds; the blood pressure was: Systolic 126, diastolic 84. The heart was pumping a bigger load per beat and the diastolic pressure had risen. The vital capacity had increased by 280 c.cm.

Instability of the vaso-motor system, whether due to adolescence or other causes, was manifested by a delayed return to the normal pulse rate after exercise. As a result of such training the disadvantages of the upright position might be overcome. Before games were taught in schools boys should be trained to breathe.

Dr. CAMPBELL MCCLURE described the two groups into which boys fell: those who were muscular and stocky in build, and those with a long thorax and abdomen and an upright heart. The muscular type was liable to be overtrained at school, and the other type was often unsuccessful at games. Athletics were over-emphasised at schools; it should be remembered how few of our children earn their living by their legs.

Dr. GUSTAVE MONOD said that in France there were no compulsory games; the chief concern of the masters, who were legally responsible for injuries to their pupils, was to persuade them to play peaceably at marbles and to avoid the dangerous sport of running. He thought the English system fairly good, but it was a regrettable fact that he saw many veteran athletes at Vichy in search of a cure for adiposity. Centenarians, on the other hand, generally appeared to live in confined rooms, to profess a marked distaste for fresh air, and to smoke and drink heartily.

Mr. MARTIN ALDERSHAW proposed a vote of thanks, which was seconded by Dr. Currie.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF DERMATOLOGY AND MEDICINE.

THERAPEUTIC VALUE OF GOLD COMPOUNDS.

AT a combined meeting of these Sections on March 20th Dr. S. ERNEST DORE, who presided, remarked that the subject presented some difficulties. For example, the ætiology of lupus erythematosus was uncertain; some regarded it as a tuberculous affection, others as belonging to the tuberculous group, still others as due to a streptococcal toxin arising from a focus in a distant part of the body. In this disease it was, he presumed, only those cases in which the tuberculous ætiology was not in doubt that were treated with gold compounds; and even then there seemed to be differences of opinion as to their value. Some regarded them as being as specific in lupus erythematosus as were arsenobenzol preparations in syphilis; on the other hand it had been stated that these gold compounds were so toxic as to be unsuitable for routine use. Some thought they gave rise to fibrosis and were beneficial on that account.

Prof. S. LYLE CUMMINS said he would not deal with dermatological conditions, although experience with these drugs in medical practice might have a definite bearing on dermatological practice. Most new preparations opened with a phase of great hope, followed by oblivion; but the gold compounds met with discouragement from the start, and only careful animal experimentation and very gradual human use had brought them through that era of doubt into a position of practical medicine. There could now be no doubt that gold was a chemical substance which exerted a selective action on tuberculous lesions, and was therefore of therapeutic value in tuberculosis. In his own hands it had given satisfactory results in all the patients on whom he had tried it. It was true they relapsed afterwards; the drug could not be regarded as a cure. It was important to obtain a clear idea of its mode of action; otherwise treatment would remain empirical. Mollgaard found that sanocrysin had an effect on the tuberculous as different from its action in the healthy, as Koch had found to be the case with his tuberculin. The action, which seemed to be on tuberculous foci rather than upon the bacilli themselves, was catalytic—i.e., it speeded up processes of cure which had before been going on slowly. When gold was given skilfully in suitable cases patients tended to improve in regard to temperature, weight, and general condition, with a decrease in sputum, and the number of bacilli excreted; in fact the sputum might dry up for the time being. The success of treatment seemed to depend on the degree to which the patient was able to neutralise or tolerate the toxic substances set free in the circulation as a result of focal hyperæmia. Hence the individual dose given must vary according to the phase of the disease. Always acting within the limits of the *dosis tolerata* (the dose which could be given to a healthy person without risk of metallic poisoning) the selection of the proper dose for the patient depended on the laws regulating vaccine therapy rather than on those applicable to drugs without a chemotherapeutic action. With the advent of heavy metal therapy in tuberculosis, it was essential to have a method of assessing cases. Among the surest guides were temperature, body-weight, the amount, character, and bacillary content of the sputum. Promising lines of work were the blood changes in tuberculosis and a better appreciation of tuberculin sensitivity. The main lessons he had learned from his animal experiments was that the disease must have become localised into a lesion for the gold to have a definite action.

Discussion.

Dr. A. C. ROXBURGH and Dr. H. CORSI presented the results of their experiences with these drugs at St. Bartholomew's Hospital. Krysolgan, they said, had a gold content of approximately 50 per cent. by weight, and the dosage varied between 0·0015 and 1·5 g. The dose of sanocrysin which had a gold content of 40 per cent. was 0·05 – 0·25 g. intravenously. In the series of cases related no local treatment was used except calamine lotion. Krysolgan was said to kill tubercle bacilli in dilutions of 1 in 100,000, and to inhibit their growth in a strength of 1 in a million; 29 g. had been used spread over 43 injections extending over 20 months. Most of the cases of lupus erythematosis treated had been of the chronic fixed type. The longest duration of the disease before gold treatment commenced was 20 years, the shortest period was one month, the average period being seven years. In one series, 19 females and 16 males were treated, and the ages ranged from 18 to 61. In all, 35 cases of lupus erythematosus were treated with gold, four cases of Bazin's disease, one of papulo-necrotic tuberculide, one of erythrocyanosis frigida, and one of pityriasis lichenoides varioliformis acuta. Of the 35 cases of lupus erythematosus, 23 were either cured or very much improved, while two were slightly improved, in five there was no change, and five were worse after the injections. Six among eight of these cases which had been regarded as cured relapsed in a few months. In 12 lupus erythematosus cases the Mantoux test was positive in nine, negative in three. Toxic reactions followed 6 per cent. of the injections, but none of these lasted long nor were they serious in nature. There seemed little to choose, Dr. Corsi said, between the two drugs, though perhaps sanocrysin was somewhat the better, as it could be given in larger doses without risk. It could not be said that the gold compounds were a cure for lupus erythematosus, but it was a great advance to be able even to improve cases of such a stubborn condition as this.

Dr. C. J. **Marshall** said he had used sanocrysin since it was first advocated, and he had seen the earlier cases treated in this way in Copenhagen. He was struck by the different reaction obtained according to the length of time that the patient had been suffering from the infection. His experience supported that of Prof. Cummins in his animal experiments—namely, that good results ensued when a definite time had elapsed between the original infection and the beginning of the treatment. When first introduced sanocrysin was used for all kinds of cases, and the speaker saw some disastrous results. His practice now was to delay the use of sanocrysin for a year from the commencement of symptoms. Dr. Marshall thought it would be a mistake to be afraid to give sanocrysin because the patient was febrile when at rest; he had had good results from it in such cases. He would not claim to have cured any patient of pulmonary tuberculosis by gold injections; he had had many cases in which the symptoms had ceased after courses of the treatment, but they relapsed, and relapse took place quicker than after constitutional treatment. But preparations of gold had proved of value in getting patients fit to undergo constitutional treatment.

Dr. H. W. **Barber** said he had treated a large number of cases of lupus erythematosus in the last few years with gold compounds, commencing with krysolgan, going on to sanocrysin, and later to solgarnol, the latter being considered less toxic and more efficacious than the other two. Though it was his custom to commence with small doses, and increase them cautiously, it was worth while, when dealing with a resistant patient, to give a "knock-out" dose, always provided no lung tuberculosis could be detected. Some of his tuberculide cases had done well under the gold treatment, but he could not claim that it had cured any of them. He had seen more toxic reactions after sanocrysin than after the other preparations. After solgarnol he had seen a generalised lichenoid rash in a patient with pulmonary tuberculosis who was brought to him because of the rash. Summing up his experience, he said the gold treatment of lupus erythematosus was satisfactory up to a point; some of his cases had remained quite well after it for two or three years, but many had relapsed.

Dr. J. E. M. **Wigley** said his experience of the gold treatment for skin diseases was entirely limited to sanocrysin, and the only disease he had treated in this way was lupus erythematosus. Of 21 cases so dealt with, only one was unaffected by the treatment; none was made worse by it. In some of the improved cases, however, the effect was only temporary He described several cases.

Dr. H. **MacCormac** said it was a pity some principles could not be formulated in regard to lupus erythematosus on the same basis as those of Prof. Cummins had in regard to general tuberculosis; it was difficult to decide whether these lupus cases were tuberculous or not. There was a big difference between lung lesions and skin lesions; in the latter, being on the surface, half the possible reacting area was cut off, and that was one reason why the dermatologist had difficulty in securing results. He had tried sanocrysin in two or three cases of lupus vulgaris, and in a recent paper Dr. Haldin Davis spoke highly of these injections for that disease. In the speaker's cases of lupus vulgaris there was definite improvement after the injections, but nothing like to the same extent as in lupus erythematosus. He regarded gold compounds as a valuable part of treatment, as they achieved improvement in cases which were resistant to every other form of application.

Dr. W. N. **Goldsmith** said he had treated by means of some gold preparation every case of lupus erythematosus which had come to him since 1925. The vast majority had reacted well, some apparently remaining cured over a period of three years. Most of them had relapsed, but they again benefited when the treatment was resumed. On account of reports of its toxic effects he had not used sanocrysin much, preferring krysolgan, triphal, orophos, and lutean. He had tried metallic colloidal gold and found it had no effect whatever. The dosage was puzzling; he had generally used tiny doses. With triphal he seldom exceeded 1·5 g., the quantity given being graded by the patient's response. Most of the cases did well, apparently in spite of the absence of a clinical focal reaction. Triphal was the most rapid in its effect and the only toxic effect he had seen was a little malaise. If a patient had a focal reaction, the speaker stopped the drug. As yet there was no guidance as to how long the treatment should be continued with the view of preventing relapses.

Reply.

Prof. **Cummins** said that the patients referred to by Dr. Goldsmith as having no definite lesion would probably be found to have small hyperæmic areas.

Dr. **Corsi** said that no knock-out doses were given in the cases dealt with in the paper he read, and even then there were a good many symptoms. The dosage used by Dr. Roxburgh and himself never exceeded 0·25 g. Möllgaard had stated that it was not the gold ion which was circulating, but a complicated ion, AuS_2O_3; it was this which had the power of diffusing through the avascular tissue which surrounded the tuberculous follicle. Possibly a pure gold ion would not have the same penetrating capacity.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

At a meeting held on Feb. 25th at B.M.A. House, Miss **Frances Huxley** being in the chair, Dr. **Françillon Lobre** spoke on the

Radiography in Sterility.

She said that the method of tubal insufflation, widely employed in the United States, was much less exact than was the radiographic method. It merely showed whether the tubes were, or were not permeable, while examination with lipiodol not only showed an obstruction impairing tubal permeability, but revealed its situation, which was a point of capital importance if reparative surgery were contemplated. The radiographic method also supplied information concerning the exact position of the uterus, its form, and the aspect of the tubal and uterine cavities. It likewise showed the condition of the mucosa and its reactions to lipiodol. These were valuable therapeutic indications for the treatment of sterility, since they show the importance of uterine and tubal spasm in a large number of the cases thus examined.

Lipiodol, she said, was well tolerated by the tubes. Rubin had described some cases in which the radiographic method was followed by peritoneal reactions, but it was possible that the cases of infection recorded had followed the use of a liquid other than lipiodol. Laparotomies had been performed upon women who had received injections of lipiodol 48 hours previously, and no sign of peritoneal inflammation had been encountered. In certain cases where mistakes in technique had permitted injections to be made under too high pressure, small collections of oil had been found in the connective tissues, but no sign of inflammation. It was necessary to keep the pressure under strict control, but with lipiodol the pressure employed might be higher (up to 30 cm. of mercury) than was permissible when air was insufflated (up to 23 cm. of mercury). Gases which were easily compressible might induce a pressure at the point of resistance higher than that at the point of escape, and it was therefore logical not to exceed an initial pressure of 23 cm. for insufflation, in spite of the fact that a much higher pressure was required to produce experimental tubal rupture. In collaboration with Dr. Jean Dalsace, Dr. Lobre had examined 230 women for sterility during the last three years. The cases examined were those in which a preliminary examination of the husband had eliminated the male factor, and in which careful clinical examination of the woman had proved negative. Contra-indications to radiographic examination were the presence of active lesions, such as those accompanying metritis, salpingitis, appendicitis, or metrorrhagia. The best time for the exploration was during the week following menstruation, from the fourth to the twelfth day. At this period adnexal reactions could be most effectively avoided, and, moreover, the risk of injecting during pregnancy was eliminated by choosing a time shortly after menstruation had occurred.

The patient had to be prepared for the examination with the greatest care. It was necessary to be sure that the cervical orifice was permeable for the introduction of a sound, since radiographic examination must never be immediately preceded by dilatation of the cervix. The examination itself must be made with the care and precautions due to minor gynæcological procedures, and the patient must remain in the hospital or clinic for a few hours before returning to her home. This was essential in order to ascertain whether the tubes were or were not permeable. A second radiogram had to be taken a few hours after the first one to see whether the shadow still remained in the tubes or was disseminated in patches in the abdominal cavity. The gynæcologist and radiologist must collaborate in the examination, which was not painful. The only disagreeable moment for the patient was when the cervix was grasped with the forceps in order to close it, since injections made to study sterility must be made under pressure. The pressure employed must be regulated with a manometer, and must not exceed 30 cm. of mercury. By prolonging the pressure sufficiently it was often possible to restore permeability to otherwise impermeable tubes. Examination must be made patiently and without haste. The passage of lipiodol into the cervix and then into the tubes, which it entered through the mechanism of the uterine contractions, must be followed radioscopically on the screen.

To avoid pain, Dr. Lobre said that she was in the habit of giving sodium bromide or benzyl benzoate for two or three days before the examination, and a suppository of hempynal was introduced one and a half hours before the examination, which was immediately preceded by swabbing the cervix with a solution of novocain. The opaque substance used was 40 per cent. lipiodol, rendered more liquid by warming on the water bath. Many instruments had been devised for injecting lipiodol, that constructed by Dr. Lobre consisting of a cannula of very malleable nickel-plated copper, bearing a tip shaped like an olive, with a terminal orifice and two large lateral eyelets. The cannula bore a flattened shoulder, situated 4½ cm. from the tip, designed to prevent it from passing too deeply into the uterus. At the other end of the sound there was a three-way cock, bearing two threaded tips. The metallic syringe was attached to one end of the tips, while upon a lateral tip was fitted a sterilisable tube containing a piston attached to which was a manometer. The patient was placed on the table lying on a draw-sheet, which enabled her to be moved easily. At the end of the table were two movable stirrups, which permitted her to be placed in the gynæcological position. The vagina was irrigated with an iodised injection, and the cervix then exposed by a bivalve speculum. It was swabbed with alcohol and grasped with the tenaculum to permit easy introduction of the metal sound. If the cervical os was large it could be closed with a large forceps, with the grasp directed backwards. If small it could be closed with the aid of one or two bullet forceps. The oil was injected slowly, at a pressure never exceeding 30 cm. Care must be observed not to permit reflux into the vagina. The speculum should then be removed and the patient pulled into the middle of the table by means of the draw sheet.

For radiography the Coolidge or Phillips tube was employed, one tube being beneath the table for examining radioscopically with the patient recumbent, and for making plates during the examination, a plate being placed on the abdomen. Plates were also made of the pelvis, both from the front and the side. When the course of the tubes was masked by the uterine cavity an oblique exposure was taken. It was possible to take anterior or posterior plates without changing the position of the patient. The plates were developed immediately and before the sound was withdrawn. In this way the work might be repeated, if not wholly successful the first time. It was absolutely necessary to follow on the fluoroscopic screen the intra-uterine course of the injected lipiodol to observe the filling of the uterus, the successive aspects of the injection, the advance of lipiodol into the tubes, and its entrance into the peritoneal cavity. These details were clearly visible by making use of the Potter-Bucky diaphragm and of a fixed or mobile grill.

Dr. Lobre then proceeded to illustrate on the screen the information which could be supplied by radiographic examination—anomalies of development and variations in the form and dimensions of the uterine cavity and in the position of the uterus. Examination showed alterations of the uterine mucosa, polyps, submucous fibromas, tumours, and other conditions which might require curettage; also the sensitiveness of the uterus and the irritability induced by application to the mucosæ of severely caustic agents. Lesions of the tubes, which might escape detection by clinical examination, could be shown, notably those causing impermeability of the cornu, or at the isthmial region. Variations of the length, calibre, and form of the tubes could also be observed. The contractions which were clearly visible in normal tubes did not occur in diseased tubes, which were distended with lipiodol, which they retained for a very long time. In certain sterile women the tubes were firmly fixed by adhesions, remaining always immobile.

Conclusion.

Such were the lessons, anatomical and physical, revealed by hystero-salpingography. However highly the method might be perfected it would never constitute a specific treatment for sterility, since some forms were not of a mechanical type. The method confirmed and precisely demonstrated the clinical findings, and likewise supplied data giving rise to new medical and surgical methods of treatment. For combating uterine or tubal spasm, we might employ antispasmodic agents, such as belladonna, atropine, benzyl, or the bromides might be used. Tubal atony might be treated with gynæcological massage or diathermy, which were equally useful in uterine displacements. If the tubes presented unduly small calibre they might first be rendered permeable by injecting them with lipiodol, and their dilatation might then be attempted by repeating insufflation for a sufficient number of times.

Restorative Surgery.—Before undertaking operative measures designed to combat sterility, hysterography should be practised. Ligamentopexy or stomatoplasty should not be attempted without being assured that the tubes were permeable. If permeability was not present an attempt should be made to restore it. Twenty operations of this kind had been undertaken by Dr. Lobre, following advice based on radioscopic findings. Thus far the results had not been satisfactory, and in no case had pregnancy followed surgical treatment. Operation had generally proved to be too late, and had revealed old and already organised lesions. In the future operation must be done earlier, indications must be more clearly defined, and technique must continue to improve. Radiographic examination not only permitted ætiological diagnosis, but often sufficed in itself to constitute the treatment of certain forms of sterility. Various statistical records had shown, like those of Dr. Lobre, that pregnancy might be obtained in about 10 per cent. of the cases examined. While this might seem a very modest result, it must be remembered that the method was resorted to when every other method had already failed. Again, the figure of 10 per cent. was a gross figure, and included the cases in which the tubes were *permanently obliterated*. In many cases tubes originally considered impermeable proved capable of receiving injections, provided that the cervix was well drawn down and the pressure continued for a sufficient time.

By following the principles described by Dr. Lobre, she and her colleague had obtained 23 pregnancies following 230 injections with lipiodol. In three of these successful cases a second pregnancy had occurred, and in one case a third. There had been only one case of extra-uterine pregnancy.

Discussion and Reply.

The PRESIDENT pointed out that the method might not be very easy to apply in private practice where facilities for re-examination after three or four hours might not be easy to obtain.

Lady BARRETT inquired how it could be ascertained with certainty that no infection of the tubes existed. Was Dr. Lobre confident that forcible injection into the tubes was safe?

Prof. LOUISE MCILROY expected to get more than 10 per cent. of successful results with douching and other methods, including insufflation. It was sometimes difficult to detect pus in the tubes, and if injections were made in the presence of a pyosalpinx trouble was to be expected. A closed tube had possibly been the subject of inflammation at some time.

Miss L. MARTINDALE asked what results had been obtained by Dr. Lobre by means of artificial insemination.

In reply, Dr. LOBRE said that some gynæcologists sent patients to a radiologist and allowed them to go straight home, but she preferred them to lie in bed for one or two days, and the examination, therefore, must take place either in a hospital or clinic. None of the patients had had a rise of temperature after the injection. She had had no successful cases after artificial insemination. The results after lipiodol were possibly better than they appeared to be, because hospital patients did not always report subsequent pregnancies.

Dr. JANE WALKER proposed, and Prof. MCILROY seconded, a vote of thanks to Dr. Lobre for coming to London to give this valuable address.

MEDICINE AND THE LAW.

Dr. Knowles's Appeal.

THE successful appeal of Dr. Benjamin Knowles raised a large issue but did not adequately determine it. Employed as medical officer by the administration of the Colony of Ashanti, he was found guilty of murder and was sentenced to death in November, 1928, by the Acting Circuit Judge, who tried the case without a jury. The death sentence was commuted by the Governor of the Gold Coast, and a year ago Dr. Knowles was granted special leave to appeal to the Judicial Committee of the Privy Council. Last November his appeal was heard and his conviction was quashed, and now in the present month the Judicial Committee has announced its reasons. The foremost and, as it seemed, the strongest of the four grounds of appeal was the contention that the court in Ashanti had no jurisdiction to try the appellant upon a capital charge without a jury. Professional men, contemplating service oversea, may indeed have realised with surprise that one of the risks of such service is the absence of the accustomed judicial safeguards. In Ashanti trial by jury is unknown. The local criminal procedure is governed by an Ordinance which prohibits the employment of barrister or solicitor. This Ordinance somewhat vaguely applies to Ashanti the law of the Gold Coast Colony; in the latter Colony, trial by jury would be imperative where the alleged offence is a capital charge; the Ordinance, however, applies the Gold Coast law to Ashanti only "so far as it is practicable and local circumstances permit." The Judicial Committee now declares that practicability and the state of local circumstances are questions which can only be determined in Ashanti on the spot. The appellate tribunal in Downing-street says it can form no opinion on these questions; their lordships assume that the proceedings against Dr. Knowles in Ashanti were in order, and that, if he was not tried by a jury, that was because a jury was not practicable in the state of local circumstances. Thus the final stage of the Knowles case contributes little to the problem which the earlier stages had forced upon public attention—the problem of the legal rights of British officials serving in remote places oversea.

It would, of course, have been administratively inconvenient if the Judicial Committee had held that Dr. Knowles should have been tried by a jury. Many existing convictions might have been invalidated; arrangements would have been required in many places to remit to more populous centres an accused person charged with a serious offence; racial issues might have been raised by questions of the selection of jurymen. Equally it would have been forensically inconvenient if the Judicial Committee had held that Dr. Knowles's trial must be reviewed upon the facts; the result would have been that their lordships would have been overwhelmed by avalanches of appeals from all over the Empire; their well-established rule is not to intervene in criminal cases unless there is either some want of jurisdiction in the court of trial, some disregard of the forms of legal process, or some violation of the principles of natural justice with its resultant injustice. The final judgment in Dr. Knowles's case avoids the inconvenience of multiplying prospective appeals; it fastens upon one point peculiar to his trial and it offers no general encouragement to other appellants. The Judicial Committee's pronouncement may thus be paraphrased: "This appeal came to us primarily on the issue of trial by jury; we reject that issue as a ground of appeal, but, having examined the proceedings, we find that the Acting Circuit Judge misdirected himself; we are not an ordinary court of criminal appeal, we are not considering if the evidence supported the verdict, we are not saying what our own verdict would have been, but we find that the Judge summed the case up to himself in a manner which would have been misleading if he had been summing it up to a jury." A shot was heard, it will be recalled, in the room where Dr. and Mrs. Knowles were alone together; Mrs. Knowles, after saying it was an accident, died of a bullet wound; Dr. Knowles said there had been a domestic fracas; she had been nagging him, and he had said that, if she did not stop, he would put a bullet in her. The Judge rejected any idea of the wound being either self-inflicted or due to accident; he held that the shot had been fired by Dr. Knowles; he decided in consequence that murder had been committed. The Judicial Committee says that to fire a shot in a fit of drunken recklessness to silence a nagging woman would be a crime, but the crime might possibly have been manslaughter, and not murder. The Judge never dealt with the possibility of mere manslaughter; the appellate tribunal, observing this omission, is not satisfied that the evidence reached the standard of proof necessary for a conviction for murder. And so Dr. Knowles has won his appeal. Persons not learned in the law may wonder that it should be so complicated a process to set aside what was evidently an unsatisfactory conviction.

COVENTRY AND WARWICKSHIRE HOSPITAL.—This institution last year treated 14,305 accident cases. There were 5090 in-patients and 24,917 out-patients. Nearly 800 patients were sent to the Alcock Convalescent Hospital, which has added £3250 to the annual expenditure. The income, at £40,895, showed a deficit of £3464. The Godiva pageant produced £5000.

Reviews and Notices of Books.

TRAUMA, DISEASE, COMPENSATION.

A Handbook of Their Medico-Legal Relations. By A. J. FRASER, M.D., Workmen's Compensation Board, Winnipeg. London: Macmillan and Co., Ltd. 1929. Pp. 524. 28s.

THIS book is written mainly for that large body of medical practitioners who are occasionally called upon to express opinions on the relation between "an accident arising out of and in the course of employment" and the disability which prevents the patient from working. The writer has been for 12 years the chief medical officer of the Manitoba Workmen's Compensation Board, but his book contains all too few of his own personal opinions; instead he gives lengthy quotations from text-book authorities on every aspect of the questions under discussion. The subjects are further illustrated by the findings of various courts in different parts of the world. Most of the decisions recorded are those of the Manitoba Compensation Board, but there are many from the English courts. It is noticeable how much more elastic are the rules governing procedure in the Canadian Workmen's Compensation Boards than those of our own county courts. In Canada each case is decided strictly on its merits, whereas here so many adjudications are bound by decisions given upon the merits of some case heard long ago.

In the first chapter a clear explanation is given of the exact meaning of "an accident arising out of and in the course of employment." The responsibilities of the employer and the employee are set forth and, what is often forgotten, the responsibilities of the workman to his master. It is explained that if an injured workmen is unreasonable in refusing to undergo operation or to attend hospital, or even to do light work, thus retarding or preventing his recovery, he may be held no longer entitled to compensation. Where disease is alleged to be due to accident, rules are laid down for the guidance of the medical jurist. To establish any causal relation between the accident and the outbreak of disease there must be a direct sequence or march of events. Where an interval of recovery occurs, the presumption is absolutely against the causal connexion with the injury. In the chapter on the heart and blood-vessels the well-known "spanner case" is given at length. In this case judgment was given for the dependents of a man who died suddenly whilst commencing to screw a nut with an 18-inch spanner. (Clover, Clayton and Co. *v.* Hughes, 3 B.W.C.C.) It was held that although the man had an advanced aortic aneurysm and was liable to sudden death at any moment, it was the slight strain of turning the spanner which was the immediate cause of the rupture of the aneurysm. The author notes that "such precedents in a large and ever-growing class of marginal cases of industrial liability have so extended the horizon of compensation law that it is difficult, or impossible, to indicate where the boundaries of industrial liability are to be drawn." This is obviously true, and it is the more remarkable that few employers seem to have any organised method of classifying their workers according to their age and physical capacity, and selecting the physically fit for the heavy and laborious tasks. In the absence of such a scheme the old man or the impaired man falls out by the way, often as the result of some single undue effort. This failure to fit together in the best way the flesh and blood components of the industrial machine explains in some measure the ever-growing army of pensioners carried by industrial boards.

If any section deserves special mention it is the chapter on hernia. The liability for hernia is always a difficult matter to decide, and the description of the condition and the rules laid down for determining its relation to accident are excellent.

The medical jurist will find real help and guidance in this book when he is confronted by a case of unusual difficulty, and practitioners will consult it with profit on any question arising out of the preparation of medical reports in cases of accident.

OBSTETRICS.

Clinical Obstetrics. By PAUL T. HARPER, Ph.B., M.D., Sc.D., F.A.C.S., Clinical Professor of Obstetrics, Albany Medical College. Philadelphia: F. A. Davis Company. 1930. Pp. 467. $8.00.

UNLIKE so many new books on subjects whose literature is extensive this is no recapitulation of standard text-book teaching. In the author's own words, it is "a story of individual reaction to obstetrical problems as they have presented themselves . . . . deductions that individual situations seem to warrant replace extended comment and multiplicity of views." Of particular interest are the author's views on Bandl's ring and difficult labour. There is little doubt that a contraction ring is much more frequently the cause of difficult labour than is generally recognised. The text is freely illustrated by thumbnail diagrams which often hinder rather than help the reader. The style is not very clear; in some places perfectly simple facts are so lost in a maze of words that the reader fails to realise that some well-known phenomenon is under discussion and imagines himself to be digesting some new and original idea.

This is no book for any but the advanced student. By careful concentration he will learn new conceptions of his problems, some of which he may accept. It is a pity that an author with so much to say is unable to present his learning in a more convincing manner.

Nurses Handbook of Obstetrics. By LOUISE ZABRISKIE, R.N. London: J. B. Lippincott Company. Pp. 535. 12s. 6d.

THIS is an American book written for American nurses who take midwifery as part of their general training. It is not written for the practising midwife, and hence the teaching is largely theoretical. It might be described as an elementary text-book of obstetrics to which has been added mothercraft and home nursing. The author seems to have given a great deal of attention to practical aspects of home nursing, and many valuable suggestions are given as to the uses of domestic articles in the labour room. Minute details are given about the toilet and clothing of the infant.

The nursing details will be read with interest and profit by midwives and social workers, but it is difficult to see a place for the rest of the book in any other than its national environment.

ECLAMPSIA.

The Improved Prophylactic Method in the Treatment of Eclampsia. Third edition (first English edition). By Prof. W. STROGANOFF. Edinburgh: E. and S. Livingstone. 1930. Pp. 154. 10s. 6d.

FEW important therapeutic measures have been less well understood than Stroganoff's improved prophylactic method in the treatment of eclampsia. At intervals, Prof. Stroganoff has published papers in the medical press of this country in which he showed that his results were far superior to any obtained by other workers. He has travelled abroad to advocate his method, but his most willing disciples have had difficulty in understanding exactly what his method entails.

When Prof. Stroganoff visited this country in 1924 his knowledge of our language was small. Realising the difficulty of accurate translation, he started at an advanced age to learn English and now presents a book written by himself in English. He begins by answering his critics and reviewing the history of the treatment of eclampsia. He then explains at length the rationale of his method, the results of modification, and discusses his own results. Twenty-five pages are devoted to typical cases, and he concludes with a detailed scheme of treatment which none could fail to understand. It is almost unnecessary to remind our readers that Prof. Stroganoff has treated 320 cases of eclampsia with a mortality of 2·6 per cent. and has had a consecutive series of 166 cases without a death. This result speaks for itself. Eclampsia is now a comparatively rare disease, yet in 1928 the Registrar-General reported that there were no less than 557 deaths from puerperal albuminuria and convulsions in England and Wales. If Stroganoff's results can be repeated in this country, this number should be reduced to a fraction of its present size.

This book is an important addition to the literature of obstetrics, and should have the widest possible circulation.

THERAPIE INNERER KRANKHEITEN.

By Prof. Dr. A. GOLDSCHEIDER. Berlin: Julius Springer. 1929. Pp. 420. R.M. 28.80.

THIS volume offers a concise review of the treatment of medical diseases from the pen of one who has had for very many years good opportunities of studying them. Prof. Goldscheider has not attempted to include more than a passing reference to either ætiology or diagnosis, and has throughout maintained an admirably practical outlook on treatment. Therapeutic methods which have little application in general practice, or those which have not yet been tried out, receive scant attention. In the introduction the author warns the practitioner against too wide a use of ready-made combinations of drugs and preparations such as appear to be so popular in Germany to-day; simplicity is aimed at in the prescriptions set out, though proprietary preparations are not unduly neglected. The book is divided into a preliminary section on general therapy including the treatment of fever, pain, insomnia, and anorexia, with a brief summary of physicotherapy. The second section on special therapy contains chapters on the treatment of diseases of all the main systems of the body in which all the commoner conditions are fully described. Children's diseases are not included. The indexing is not very full and there is no means of referring directly to any special drug. English readers will be compelled to transpose prescriptions from the metric to our own system. This volume provides a balanced and concise account of practical treatment and is well representative of the present-day outlook of German physicians.

IMMUNOLOGY OF PARASITIC INFECTIONS.

By WILLIAM H. TALIAFERRO, Ph.D., Professor of Parasitology, University of Chicago. New York: The Century Company. 1929. Pp. 414. 25s.

OWING to the dominant morphological viewpoint adopted by many past investigators, the value of immunity studies in protozoology and helminthology has been unduly depreciated. By grouping in orderly fashion so heterogeneous a collection of immunological data as is presented in this volume, Prof. Taliaferro has made an important contribution to medical literature and one which should focus the attention of tropical workers in particular on the deficiencies and gaps in present knowledge of this important subject.

Many phases of parasitism and immunity are unfolded in this volume, including some interesting comments on the environment of parasites compared with free living animals. Special chapters are devoted to lysins and reproduction-inhibiting antibodies in relation to the types of infection in trypanosomiasis and malaria, and also to the protective and curative action of immune sera in certain protozoan infections. The cellular basis of immunity and the nature and production of immunity in parasitic diseases are dealt with.

The serological reactions reviewed include the complement-fixation and precipitin tests; by these means specific antibodies have been demonstrated in many protozoan and metazoan infections. In man they are of proved clinical value only in hydatid disease and schistosomiasis, though in the author's opinion there seems to be considerable promise that they may be applied to amœbiasis and trichiniasis. Three types of skin reaction are described all of which depend upon a hypersensitive condition of the host. Of these there is little evidence that true local anaphylaxis or the Arthus phenomenon ever occurs in parasitic infection, but unquestionably both the immediate wheal and the delayed response occur in man and animals infested with helminths. As these reactions are not necessarily correlated with humoral antibodies, skin tests and serological reactions should be conducted simultaneously.

This volume is written with judgment. It is well indexed, and possesses an admirable bibliography.

PLANT BIOLOGY.

By H. GODWIN, M.A., Ph.D. London: Cambridge University Press. 1930. Pp. 265. With 67 figures. 8s. 6d.

THE loyalty of Cambridge students of elementary botany to Prof. A. G. Tansley's book must be rather seriously strained by the publication of this excellent introduction to the study of plants by another Cambridge teacher. It is written from the physiological rather than the anatomical point of view by one who is a physico-chemist rather than a biologist, and it gives a clear and interesting account of what plants are and how they live. Where the author goes wrong is in deliberately trying to adapt his book to the use of medical students and using as illustrations examples which he supposes are of particular moment in medicine. This leads him into fields with which he is obviously not familiar and his account of pathogenic bacteria is misleading in many particulars. Fermentation reactions are described as the "only" means of separating colon and typhoid bacilli; spores are characterised by "taking stains easily"; the chief "significance" of bacteria to man is their power to cause disease, though of course the author knows quite well that human life would be impossible if bacteria did not run the nitrogen cycle; bacteria are said to cause their ill-effects "sometimes by the direct breakdown of the body tissue as food material." If the student remembers any of this, it will have to be undone by his bacteriological teacher, and Dr. Godwin gives yet another example of the futility of trying to make the medical curriculum overlap upwards. By so much as chemists try to teach physiology or physiologists purport to teach pathology or pathologists pretend to teach clinical medicine, they are discharging their proper function badly and their teaching will be bad. Overlapping must be downwards, not upwards.

DR. AND MRS. JOSEPH COATS.

Compiled by their Daughters. Glasgow: Jackson Wylie and Co. 1929. With 13 plates. Pp. 330. 5s.

Joseph Coats (1846–1899) was the first professor of pathology in the University of Glasgow, and he wrote one of the earliest English text-books of pathology. He was also a good man and had a good wife, who survived him for 28 years. Their daughters have put together a book of remembrance which makes a delightful tale of happy, useful, friendly lives. It will be, of course, particularly interesting to their own circle, which was a large one; there is perhaps not quite so much about Coats the pathologist as we should wish. But how a throat specialist who had visited Recklinghausen taught his university that there was a new discipline which they would have to recognise is a significant piece of the history of the medical sciences. Everyone knows how fruitful Coats's work has been in Glasgow; and this book reminds us how young pathology is.

THE LANCET.

LONDON: SATURDAY, MARCH 29, 1930.

THE OPHTHALMOLOGICAL SOCIETY:

FIFTIETH ANNIVERSARY CONGRESS.

THE Ophthalmological Society of the United Kingdom celebrates at its Congress next week the fiftieth year of its existence. It owed its origin to a small but distinguished band of ophthalmic surgeons who were in the habit of meeting, rather casually and from time to time, at Moorfields. A more formal meeting at the house of Mr. Bowman (later Sir William Bowman), in February, 1880, resulted in the definite formation of the Society whose first meeting took place on June 23rd, 1880, under the presidency of Mr. Bowman. One of the members of the inaugurating committee is still with us in the person of Sir Thomas Barlow, who has kindly undertaken to respond to the toast of the Society at the Jubilee Banquet, which takes place on Friday, April 4th, in the Fishmongers Hall. Among the members of the first Council of the Society, in addition to the President and Sir Thomas Barlow, were many who had already, or who subsequently achieved distinction in the world of medicine. George Critchett, Jonathan Hutchinson, Hughlings Jackson, and Swanzy were Vice-Presidents; Edward Nettleship and Stephen Mackenzie were the Secretaries; and Gowers, Brudenell Carter, Hulke, Henry Power, and Waren Tay were some of the members of the Council. Of the 114 original members of the Society, 11 still survive, but distance and in some unfortunate instances the physical disabilities of age will prevent the majority of these from attending the meetings next week, but Sir George Berry and Mr. J. B. Lawford have both promised to come and, with Sir Thomas Barlow, will represent the founders. A number of distinguished foreign ophthalmic surgeons will also be present as guests of the Society, among them being Prof. van der Hoeve, President of last year's International Congress at Amsterdam, Prof. Márquez, President-elect of the next International Congress to be held in Spain in 1933, Dr. de Schweinitz and Dr. Morax, both aforetime Bowman Lecturers, Prof. Lundsgaard, Chairman of the International Council of Ophthalmologists, and Prof. Terrien, of the Hôtel Dieu, Paris. A programme of the Annual Congress, to be held next week, will be found on p. 729.

The 49 published volumes of the Transactions are ample evidence of how fully the Society has borne out its original aspirations. In the first volume appears Waren Tay's description of the disease now known as amaurotic family idiocy. Later volumes showed the first cases of the allied form, the Batten type of cerebro-macular degeneration. In the first volume, also, is the most admirable account of optic neuritis in cerebral lesions by Hughlings Jackson, which can be read with profit at the present time. This subject continues to bulk largely in the early volumes. In Vol. III. appears Lawford and W. Edmunds's paper on the pathology of optic neuritis, while further papers on the same subject in Vols. IV. and V. show how thoroughly the new group of workers were justified in the formation of a group of intensive workers. Indeed, to go through these transactions volume by volume, picking out papers of importance which have contributed to the advance of special knowledge, would amount to a syllabus for an exhaustive system of ophthalmology. The Bowman Lectureship was instituted in 1885 to commemorate the first President and the first lecturer was Dr. Hughlings Jackson. Many men of great distinction, British and foreign, have given this lecture, and this year, Sir Arthur Keith, President of the British Association, will discharge the office appropriately, speaking on "The Genius of Sir William Bowman."

The obvious value of the new Society was recognised almost at once, as the columns of THE LANCET show, and its activities found expression at a time when the level of ophthalmological knowledge expected from the young practitioner demanded an elevation which it was not receiving. It became felt almost immediately that the Society would be of great assistance in bringing about needed reforms and thus it assumed in its earliest days its great position. In 1912 the question arose of fusion with the Royal Society of Medicine, and for a time the future of the Society was in doubt. The arguments for the amalgamation were strong, if only because of the close and perpetual inter-relation between ophthalmology and the whole of medical science; and some such view as this did find expression among certain professional leaders at the time of the formation of the Society. But when the Royal Society of Medicine was founded it was felt that the tradition of good work so well and truly laid should not be lost, while it might be submerged if the Society lost its identity in the greater Society. The decision taken then has proved a wise one. The Society made itself responsible for running an Annual Congress and agreed to leave the monthly meetings to the Section. That arrangement has resulted in building up a strong Section of Ophthalmology in the Royal Society of Medicine; and the Ophthalmological Society, despite the fact that it has budded out into numerous off-shoots, is itself now stronger than ever, and works in complete harmony with the Section. If we may judge from the quality of the work that is being done at present by some of the younger members of the Society, it will maintain its place well in the forefront of the ophthalmological world and produce in the next 50 years work in every way worthy to stand beside the work of the last 50 years.

MENTAL TREATMENT BILL AND THE BOARD OF CONTROL.

THE progress of the Mental Treatment Bill in Committee has been disappointingly slow, nevertheless the main principles of the Bill seem secure and, unless there be unforeseen delay, it may be expected this valuable alteration in the law will be passed without serious amendment. The chief provisions—the admission of voluntary patients in public mental hospitals, the provision of temporary treatment for persons not objecting to it, and the obligation placed on local authorities to provide treatment for early or incipient cases of mental illness—have already been passed. Whilst there is certainly ground for criticism regarding details, we have no doubt that the measure will provide treatment for a large number of persons now drifting towards insanity without any care or treatment, and that many of these will recover without certification and without any Justice's Order being required. In the future we may expect that recent cases will either be treated as voluntary patients or under the new clause providing temporary treatment, and it is satisfactory that this treatment will be available for the poor as well as the rich. We presume that only in the case of those refusing treatment will the present procedure be necessary. For unrecovered cases, still needing care, certification will be continued. The new feature of the temporary treatment clause lies in the fact that persons unable to decide for themselves can be received in a hospital, nursing home, or private house on the recommendation of two medical men, one of whom must be approved by the Board of Control. The place of treatment must in like manner be approved by the Board. It remains to be seen how this will affect medical practice, and whether the same unwillingness to recommend will obtain as that which exists in regard to certification. A new amendment was passed last week which required the medical man to give his reasons for his recommendation, and this brings the procedure very close to certification, and, moreover, greatly adds to the difficulty of the practitioner should at some future time his action be called in question. How far Clause 16 will effectively protect him from vexatious ligitation is not clear.

It was decided in Committee to discontinue the appointment of honorary commissioners, but it was agreed to consider the appointment in some other places of unpaid assistance. One reason for this was the desire to reduce the number of senior commissioners who will in future constitute the Board of Control. Perhaps some who voted against continuing the present system objected on principle to unpaid public servants. We think this decision unfortunate. When one considers the large amount of devoted work done by unpaid commissioners in the past, it seems a mistake not to take advantage of their service. Especially in respect to mental deficiency administration have honorary commissioners done an immense amount of work. These appointments make it possible to secure the services of retired commissioners and other experienced public men who cannot accept the obligations of a salaried post. We consider they add to the status of the Board and give public confidence in its decisions. The other matter which is of grave importance is the constitution of the Board itself. It has been decided that it shall consist of five senior commissioners, of whom one must be and two may be medical men. For many years the Board of Control has not been able to cope satisfactorily with all the duties laid upon it by statute. Its numbers have not increased proportionately to the increase of patients and all the extra work involved in administering the Mental Deficiency Act. Now it is to be given additional work. Under the Bill, the Board of Control will have to approve hospitals and homes for patients admitted voluntarily or, under the temporary treatment clause, must approve the doctors giving recommendations. Moreover, notifications, recommendations, and reports will bring to the office an additional torrent of papers that will require expert examination, and, besides all this, temporary patients will have to be visited, and the working of the new provision directed and supervised. Whilst it may be probable that many of the duties of the Board can best be performed by a small body which can meet frequently, we cannot but fear that the grading of the commissioners into two classes may have a prejudicial effect on what is really the most important part of their work. We believe it is necessary that the Visiting Commissioners should be men and women of standing so that their recommendations may carry weight with local authorities. Their position is essentially different from that of inspectors, in that they are appointed by the Crown to safeguard the liberty of individuals, to protect insane persons from neglect or cruelty, and to prevent suffering through the parsimony of local authorities. The KING is the protector of all who are not of sound mind, and he appoints the commissioners to act for him in this respect.

At first it may be thought that mental disease is only a department of medicine, and that mental hospitals should be under the direct supervision of the Minister of Health in the same way as poor-law hospitals and infirmaries. But the Royal Commission unanimously reported that the Board of Control should retain its independence, except that the majority of its members should be appointed by the Minister of Health, and he should represent it in Parliament. The present Bill does not actually alter this, but in the course of the debate several remarks were made which gave the impression that it was really desired that the Board of Control should in effect become a department of the Ministry of Health. We realise that in 1845, when the then Lunacy Commission was instituted, there was no Ministry of Health, and it is extremely unlikely that, in modern conditions, the old abuses will recur. It is, however, certain that to some extent evasion of the law will continue, and that "back parlour" treatment for private profit will occasionally occur. It is also certain that some local authorities will be slow to realise their responsibilities towards the insane and defectives, and unless the Board of Control and the Visiting Commissioners be such as command confidence there will be danger that neglect and even abuses may arise. Therefore we would urge that, whatever may be done, the Visiting Commissioners, medical as well as legal, should be persons of a standing that can command respect from local authorities and the highly trained medical officers in control of the mental hospitals. We would deplore any step which may weaken the authority of these public servants. Their status and conditions of appointment must be such as will attract men and women with professional attainments of a high order.

MEDICAL PATENTS.

REFORM of British patent law has been in the minds of many groups of people during the past few years, and while, no doubt, it is the manufacturers of dyestuffs and chemicals who most desire to see some change, it is significant that a representative committee of chemists should devote one-third of a long memorandum to the question of medical patents. This memorandum is summarised on p. 718, in so far as therapeutic and biological substances are concerned. The medical profession has itself from time to time expressed strong views on this subject, its attitude, as the chemists' memorandum points out, being mainly against the patenting of therapeutic substances. The objection rests in principle on two grounds. First, that it is undesirable for a medical man to derive financial benefit from any discovery made for the relief of human suffering; secondly, that to patent any such discovery might lead him to take unfair advantage of colleagues. The manufacturer's point of view is different, but it requires close attention, inasmuch as medical discoveries of a therapeutic nature are useless without active and sincere commercial coöperation. The manufacturer is in favour of restriction because it enables him to put on the market substances requiring great expenditure on plant, time, and personnel. While the medical inventor may be able to sweep aside any thought of financial gain from his discovery, it is absurd to expect the manufacturer to make the substance invented unless he can look to a reasonable profit from his enterprise. It would seem at first sight as though the main problem facing the Board of Trade's Patents Committee is to reconcile these opposing forces—the financially disinterested medical inventor on the one hand, and the profit-making manufacturer on the other. Each of them is called upon if the British public is to obtain the full benefit of scientific work. Unless there is some liaison between them, it is quite feasible for a foreign manufacturer to investigate an unpatented process described by one of these disinterested English workers, and by discovering a minor modification in the final stages to obtain a patent which would exclude the British manufacturer from starting to make the substance in question, or from going on if he had already begun. This has occurred many times. Whilst the position of the manufacturer is clear enough, the public may not find it so easy to understand the attitude of the medical inventor. The bodies which have had the matter under consideration, whether it be the Medical Research Council, the Ethical Committee of the British Medical Association, the British Science Guild, or the Association of the British Chemical Manufacturers, all assume that the medical man does not desire to make money from his invention. This attitude may reflect that of the medical profession without being exactly logical. It does not necessarily follow that the medical man who patents a discovery would be biased in his treatment of patients nor, perhaps, is that so much the apprehension as that he should swell his clientèle by the attraction of novelty. The type of medical man who discovers a therapeutic substance, capable of manufacture on a large scale and of sufficient importance to be protected from foreign competition, is unlikely to be engaged in medical practice. In ninety-nine cases out of a hundred he will be a worker in one of the scientific departments of a university or hospital, and the very nature of his discovery would demand that he should devote his whole time to the research in question. It is highly improbable that a physician, surgeon, or general practitioner would make a discovery of this type. The strictly professional attitude —at any rate hitherto—may be seen, therefore, to guard against what is in theory a great danger, while it may have no existence in practice. Nor can a medical man who makes money out of a scientific discovery be reproached for turning human suffering to financial gain, for in every branch of medical practice it is success in relief of suffering that brings position and emolument.

The middle way, now unanimously accepted by all the committees, is what is termed the system of dedicated patents. The medical man who discovers the preparation of a valuable therapeutic agent will patent the substance itself, and its method of manufacture, through an authority to be called the Public Patents Trustee. The patent will be dedicated to the British public, the patentee himself deriving no financial benefit from his discovery. The Trustee will issue licences for the manufacture of the substance to commercial firms, who will sell it to the public. The first free licence, it seems, will be granted to the patentee or to his nominee, but it is not quite clear whether or no this gives the patentee the opportunity of making a little money through his nominee. That the medical patentee will be entitled to have some say in the foreign rights follows from the provision: "the inventor will have the first option of taking out foreign patents, and if he exercises this he can deal with foreign royalties in the usual way." On the manufacturer's side, the Trustee will decide to whom the licence should be given, and in this delicate duty he is to be assisted by an advisory committee. It is the intention of the Joint Chemical Committee that royalties imposed by the Trustee should be of a nominal character, and should not more than suffice to cover the expenses of administering the dedicated patent. In other words, the medical inventor who dedicates his patent to the British public, after having worked early and late to obtain this valuable information, forswears all financial gain—with the possible exception of some slight advantage through the free licence and foreign rights. The medical inventor, or the hospital or university which has financed him, has borne the whole expense of his investigation, and the British public accepts the benefit. The manufacturers are given the right to make the substance, and the royalties imposed by the Trustee are to be "nominal." On the other hand, if a non-medical person were to come to the manufacturer with a patented process, he would not demand royalties of a purely nominal character. He would say that he had a very valuable preparation, that he had expended his brain, time, and money on producing the discovery for a patent, and that the manufacturers must be prepared to pay him royalties. If they decided that it was a good preparation, and one likely to bring in money, they would come to terms. When they deal with a medical man, they are prepared to take full advantage of the fact that he wants no royalties. The proposals as they stand savour of the heads-I-win-tails-you-lose type.

It is unfortunate that all the discussions on patent reform in connexion with medicine should turn on the financial question. The doctor must not make money, the manufacturer must be guaranteed his. Surely there is a wider principle than this at stake; that the public be supplied with really active preparations. It matters little who is obtaining a dividend of 5, 10, or 15 per cent. on the sales of (let us say) an endocrine preparation. The essential point is the potency of the preparation. Why should we not insist that any substance made under a dedicated patent should automatically be placed under the Therapeutic Substances Act, and that any firm operating under a dedicated patent should be bound to submit their products to the authority constituted under this Act? By this means doctor and public alike would be certain that the firm in question were producing an active substance in accordance with the principles laid down in the original publication. Again, should not all these committees recognise that, if the medical man is prepared to forego his financial right, the price of the final article as sold by the manufacturers should be controlled by the Trustee, more particularly so when they recommend that the royalty should be "nominal." While the patenting of dyes and heavy chemicals may be a purely financial problem, the manufacturers should realise that in medical matters the first and final consideration is the health and welfare of the general public. If the patent reform proposed is to ensure that substances manufactured under the scheme will be inspected and guaranteed accurate in accordance with the original specification, then it is a laudable scheme. If on the other hand it is merely concerned with the financial aspect of the situation, then the body of medical opinion must look upon it with grave doubt.

Annotations.

"Ne quid nimis."

PROBLEMS OF A CITY HOSPITAL.

CAREFUL students of hospital reports and statistics cannot avoid the conclusion that the outstanding difficulty of the voluntary hospitals is no longer the finance of the year, but accommodation. Though there are still deficits, they are smaller and less numerous, generally speaking, than a few years ago; but as this anxiety has lessened it has been replaced by the problems, often acute, of finding beds for waiting patients. The rather rapid growth of the "hospital habit" is not the only cause of the congestion, and the relation between cause and effect is neatly exemplified in the report for 1929 of the Royal Victoria Infirmary, Newcastle-on-Tyne, which may be taken as a typical, as it is certainly a model, city general hospital. The beds at its disposal —572—are obviously inadequate for an agglomeration of population such as that of which Newcastle is the centre, and it is not surprising that 22 extra beds have to be provided every day, a number sometimes considerably exceeded. In every great industrial centre there are many accidents, and last year Newcastle Infirmary treated over 22,000 such cases. That, of course, means pressure upon the out-patients department, rather than upon beds, but 1470 of these cases were the direct result of accidents with motor vehicles, and 436 of these patients —roughly, one third—had to be detained. The net result was the occupation of 20 beds each day throughout the year, which almost exactly accounts for the extra beds. Yet, revision of the list notwithstanding, there were 2603 patients waiting for these beds. The annual cost of each was £160 8*s.* 8*d.*

Overcrowding is one of the worst and most intractable troubles with which the hospital administrator has to deal. It impedes work which very often cannot endure impediment without evil results, and adds to the wear and tear of nerves and tempers which need to be exceptionally calm and serene. Yet it is not at Newcastle alone that these trying conditions exist; they are general throughout the country, and only experience will show to what extent the pressure will be relieved by that throwing open of the poor-law hospitals which takes effect next week. The relief is mathematically conditioned by the average number of vacant beds in these institutions. In some there are many; in others very few, but the adoption of the county or the county borough as the unit should facilitate the mobilisation of hospital resources. It is to be feared that, in face of the growing pressure, this source of help will not fill the gap for any substantial period, and at Newcastle, as in other great towns, this is clearly recognised both by the infirmary and the corporation. The one is perfecting its arrangements for utilising the premises vacated by the Ministry of Pensions, part of which will provide 86 pay-beds; the other proposes to set aside a portion of the Wingrove poor-law hospital to supplement the infirmary accommodation. Yet, undismayed by the existing pressure, Newcastle Infirmary is about to establish a complete orthopædic department as a separate unit of 50 beds, with its own out-patient annexe, and in view of the attention now being paid to orthopædics, and the comparative scarcity of machinery for dealing with it, there are not likely to be many empty beds in the new unit.

Enterprises such as this involve heavily increased expenditure, and it is beginning to be generally realised that the most certain and fruitful method of meeting enhanced current expenses is by the establishment of contributory schemes. The desirability of setting up such a scheme at Newcastle Infirmary has been discussed, but the Parliamentary Committee of the Newcastle Corporation has gone further and actually made the proposal. It seems no longer to be possible to confine any contributory scheme which, like the exceedingly remarkable Birmingham one, is pooled for all the hospitals of an area, merely to the voluntary hospitals. In a completely coördinated plan the municipal institutions must assuredly share in the advantages of a system which confers rights while saving self-respect.

FURTHER PROVISIONAL DEATH-RATES FOR 1929.

PROVISIONAL death-rates per million population for England and Wales during the year 1929 have been reported by the Registrar-General as follows:—

	Males.	Females.	Persons.
Respiratory tuberculosis ..	938	661	793
Other tuberculosis	185	148	166
Cancer	1386	1483	1437

The maternity mortality in 1929 per 1000 live births based on deaths primarily classed to puerperal conditions is given provisionally as follows:—

Puerperal sepsis	1·80
Other accidents and diseases of pregnancy and parturition	2·53

POLYCYTHÆMIA.

Dr. F. Parkes Weber and Dr. O. B. Bode[1] have done good service in systematising the conditions characterised by increase in the number of the red cells in the blood. They classify the polycythæmic states under the headings of erythrocytosis or secondary polycythæmia, erythræmia, hypertonic polycythæmia, and erythroleukæmia. In the first class fall all those cases of increase in the red cells following a response of the hæmopoietic system to a call for more tissue-oxygen. The physiological response is seen in the polycythæmia of high altitudes, but the same mechanism accounts for polycythæmia in certain pathological conditions such as stenosis of the pulmonary arteries, syphilitic pulmonary arteriosclerosis, and heart failure. Even in certain types of case which the authors class as "toxic"—notably the polycythæmia seen in chronic carbon monoxide poisoning, and in methæmoglobinæmia due to poisoning by the coal-tar derivatives—the same mechanism is probably at work. All cases of this type they would group under the name of erythrocytosis. Their treatment must naturally be directed towards the underlying causes.

Cases belonging to the Osler-Vaquez syndrome, which come under the heading of erythræmia, are distinguished from the foregoing by the presence, besides polycythæmia, of a grossly enlarged spleen, and the absence of any discoverable cause for the increase in the red cell count. They think this condition a primary disorder of the hæmopoietic system, comparable in every way to the leukæmias. That it is not confined to the erythrocyte-forming cells of the system is shown by the fact that the white cells, especially the polymorphs, are always increased in number, and that myelocytes and other abnormal forms of white cell may be present. If the leukæmias are to be regarded as representing a change in the blood comparable to malignant change in the fixed tissues—and there is much to support this view—erythræmia may be looked on as a malignant change mainly affecting the erythrocyte-producing portion of the hæmopoietic system. Evidence of the close relationship of erythræmia to leukæmia is afforded by those cases which start with the blood picture of erythræmia and finish with that of myeloid leukæmia with pronounced anæmia. These cases Parkes Weber and Bode would group under the separate heading of erythroleukæmia, but there seems little necessity for this further group. All cases of erythræmia may be regarded as potentially leukæmic. Frequent and copious bleeding and phenylhydrazine are regarded as the best means of treatment, and a special warning is given against splenectomy.

---

[1] Polycythæmia, Erythrocytosis and Erythræmia. By F. Parkes Weber and O. B. Bode. London: H. K. Lewis and Co., Ltd. 1929. Pp. 34. 3*s.*

It is doubtful if the third group of Parkes Weber and Bode—polycythæmia hypertonica—needs to be differentiated from the first. Polycythæmia associated with high blood pressure was first described as an entity by Gaisböck, and on the continent rejoices in an eponym. High blood pressure is found in many cases of polycythæmia, both secondary and essential, and renal disturbances are not uncommon. All cases of polycythæmia might perhaps be brought together under the first and second of the authors' groups.

ANALYSIS OF PSYCHOTICS.

THE discussion at the Royal Society of Medicine on psychotherapy in mental disorder, which we reported last week (p. 625), revealed a divergence of view which may be explained in part by differences in scientific method and in part by differences of training and experience. On the one hand are psychiatrists whose work has been concerned principally with institutional material; on the other hand are psycho-analysts who for the most part have not had much to do with the type of psychotic found in mental hospitals and whose training in psycho-pathology has been predominantly on Freudian lines. Dr. Devine from a wide experience of confirmed psychoses again advocated the view, so ably expounded in a recent book, that the basic cause of psychotic manifestations is primarily "organic." He uses the term "organic" in a special sense as pertaining to the vegetative aspects of the organism, not necessarily the same as the usual clinical sense of "structural." With such a point of departure it is clear that the modifications which psychotherapy tends to produce—primarily at the psychological level of the integrated activities of the organism—cannot be considered as cardinal but must be regarded as symptomatic palliatives. Psycho-analysts, however, feel capable of explaining all the characteristic psychotic symptoms in psychological terms alone, deduced from psycho-analytical interpretation of the mental processes involved. The fact that these interpretations have not received by any means a universal acceptance, and that even those psychiatrists who are sympathetic towards much that is psycho-analytic are still sceptical of some of the most fundamental of the assumptions involved, naturally does not deter psycho-analysts from pursuing their working hypotheses. Dr. Glover refrained from doing much more than defining the ways in which by the special psycho-analytic methods of approach psychotics may become accessible to psychotherapy. He explained that the cases so far dealt with were too few and the time that has elapsed too short to justify final claims. We might add that a perusal of Abraham's pioneer psycho-analytic work on some depressive psychoses, mentioned by Dr. Sylvia Payne in her contribution, does not compel conviction of the validity of his interpretations.

But there is a viewpoint which in the discussion between organicists and psycho-analysts hardly received sufficient attention, although it is widely held among continental psychiatrists. For example, a distinction has long been made between the "fundamental disease process" and the "accessory symptoms" of schizophrenia. The fundamental process would correspond to Devine's organic substratum, while the accessory symptoms are presumably accessible to psychotherapy. Similar interpretations would make psychoses of manic-depressive type and also many cases of idiopathic epilepsy explicable on the basis of peculiar, sometimes inherited, responses to psychological factors. Here also psychotherapy should have a fruitful application in the resolution of the precipitating conflict. Another view regards schizophrenia, paranoia, and paranoid conditions as frequently the result of habit-deterioration, the psychotic development being traceable in the life-history, where traits of personality emerge of a type that leads to increasing maladjustment and finally to the rupture of compensation that we call the psychosis. Looked at in this way the therapeutic problem of the psychoses, as Dr. Gillespie pointed out, seems more hopeful, principally from the preventive aspect. This would involve working with children and adolescents in the pre-psychotic stages. Some confirmation is forthcoming both from recent psychiatric experience with children and also, it is interesting to find, from some instances of the psycho-analysis of children such as those quoted by Dr. Melanie Klein.

What the discussion principally brought out is the need for much closer rapport between the different investigators, psychiatrists and psycho-analysts. It is unfortunate that there should be such a division of opinion as springs from imperfect collaboration. It is clear also that there is much room for research into the predisposition to psychosis and into the possibilities of modifying the various factors while they are in the making. It would be most useful if a number of people, apparent candidates for psychopathy, could be followed and studied from childhood into adult life. Furthermore, an attempt should be made to disentangle the congenital or inherited and presumably less modifiable predispositions from those which are acquired and presumably more modifiable. Our county asylums, drawing upon a defined area of population, should be peculiarly well situated for the study not only of mental disease in families but of the inheritance of individual traits and tendencies. In the psycho-pathology of the developed psychoses themselves there remains a wide field for study. The relative dearth of articles on this topic published from mental hospitals in this country is in striking contrast with the number of researches on the physico-chemical condition of mentally sick patients. The problem of accessibility has not been sufficiently studied; a continuous search should be made for a technique of access. When these questions have been better explored it will become possible to discuss treatment, psychotherapeutic and otherwise, more effectively.

PULMONARY ASBESTOSIS.

IT is now recognised that the inhalation of dust generated in the manufacture of asbestos often gives rise to an insidious and progressive pulmonary fibrosis which is distressing in its effects and disastrous in its consequences. The value of asbestos depends upon its well-known resistance to heat and to the action of strong acids and alkalis. Its importance in the manufacture of fire-resisting articles, whether designed to protect against risk or for use in connexion with machinery, and the absence of any efficient substitute is the cause of ever-increasing demands upon the factories where the fibre-containing rock is crushed and the fibres spun and carded. The number of persons employed in the factories is already large and, as Sir Thomas Oliver[1] points out, many of the workers are young. In the past too little attention has been paid to their welfare, and the need for rigid standards of protection is urgent if further suffering and loss of life are to be prevented. The effects of the inhalation of asbestos are due to the silica which it contains, but the resulting fibrosis differs histologically from the nodular form seen in other types of silicotic lung—e.g., in gold miners' phthisis. The whorled formations seen in the latter are absent and are replaced by a diffuse fine interstitial pneumonia. The difference is also reflected in radiograms of the two conditions, the gold miner's lung showing scattered dense rounded opacities which contrast with the fine basal mottling and linear striæ which are characteristic of the asbestos worker's lung.

---

[1] Oliver, T., Arch. f. Gewerbepath. und Gewerbehyg., 1929, i., Heft 2.

A peculiar feature of pulmonary asbestosis is the presence of the so-called asbestosis bodies. These were discovered by Prof. Matthew Stewart in the sputum of workers suffering from the disease, and they have been demonstrated by a number of investigators in sections from the lungs, and in lung juice removed during life by exploratory puncture or expressed at autopsy. The asbestosis body, which bears a curious resemblance to a minute crustacean, consists of a central core of asbestos fibre which appears to be embedded in a series of discs. One end of the fibre is often buried in a bulbous extremity, and this with the succeeding discs produces the appearance of a minute screw. The nature of the aggregation around the central spicule is unknown, but Gloyne[2] has been able to demonstrate the central fibre by exposing the containing body to the action of sulphuric acid.

THE SCIENTIFIC EXAMINATION OF PICTURES.

THE famous Italian pictures, which returned to their various homes last week, after being on crowded view in Burlington House for the past two months, evoked enormous general enthusiasm and, as was inevitable, certain discussions on the attributions. For more than ever is the authenticity of old masters becoming a serious financial matter, while the prices for genuine canvasses soar upwards under American desire of possession. It is significant of much that is happening in clinical medicine that recourse should be had to exact scientific methods in diagnosing the period of a painting and possibly the actual painter—critical acumen is taking its place with *tactus eruditus* as something personal whose value can be added to by employing the methods of laboratory technique. Dr. A. P. Laurie, professor of chemistry to the Royal Academy of Arts, has contributed to this month's issue of *The Analyst* an article—a record of a recent lecture delivered before his Society—upon the identification of pigments used in painting at different periods, in the course of which he gives a brief account of other methods of examining pictures. The technique employed closely resembles that of the pathological laboratory, and it is not suggested that the verdicts of these investigations are to take the place of the judgments of the instructed. Knowledge of the art of painting, its history, and the manners of the various schools, of brushwork, and of idiosyncrasies of well-known executants will remain the medium of identification, but the chemist and the radiologist can be drawn upon for assistance. Dr. A. Martin de Wild (see THE LANCET, Nov. 2nd, 1929, p. 932) has gone over the ground, when investigating the pigments used by the Dutch and Flemish masters from the fifteenth century onwards, and such a system of inquiry may give art critics a feeling, shared by many medical practitioners, that, with a disputed diagnosis as a possibility, the calling in of the chemist and radiologist is a measure of ordinary prudence.

PYELOGRAPHY WITHOUT CATHETERISATION.

GOOD results are claimed[3] for a new method of examining the urinary tract by means of a preparation called uroselectan. Since the advent of cholecystography urologists have been stimulated to search for a similar method applicable to their specialty. After trying various substances Lichtenberg and Zwick have hit upon an iodide compound which they call uroselectan, and it promises to be very useful for the purpose. As it is badly tolerated by the stomach it has been given by intravenous injection. Two injections are made at three minutes' interval, the first 40 c.cm. and the second 60 c.cm. of a 40 per cent. solution of the drug. Films may be taken a quarter, three-quarters, and one and a quarter hours after the final injection, and it is said that as a rule good shadows are obtained of the whole urinary tract. If, however, the renal function is depressed no shadow may appear for six hours or more, and the rapidity with which a pyelogram is obtained is therefore a rough guide to the efficiency of the kidney. The method may be regarded as a definite advance in urology. Where it is sufficient for diagnostic purposes it is obviously a great gain to the patient who is spared ureteral catheterisation, and it should also be useful in those cases in which the catheterisation is attended by special difficulties, as in advanced tuberculosis of the bladder. Uroselectan has already been tried by a number of surgeons in Germany and France, and is being tested in England. Mr. Frank Kidd records some observations in the current number of the *Journal of Urology*.

A FRIPP MEMORIAL.

A PROPOSAL has been made in the public press that a memorial to the late Sir Alfred Fripp should be instituted to perpetuate his memory, and we have received from the popular novelist, Major Hay Beith, an outline of the scheme which has been set in hand. It is proposed to invite public subscriptions to a fund to be devoted to the development and extension of the Children's Department of Guy's Hospital, the endowing of cots, the building of a new ward, or in such other manner as the governors of the hospital and Sir Alfred's own relatives may decide. The trustees of the fund will be Lord Lonsdale, Mr. Wilfred Godfrey, and Major Hay Beith. Subscriptions may be sent to, and will be gratefully acknowledged by the Hon. Secretary, the "Sir Alfred Fripp" Memorial Fund, 145, Cheapside, London, E.C.2. Major Beith writes: "Two characteristic donations have already been received by us—a cheque for £1000 from those truly practical philanthropists, the Froth Blowers, and a sum of 10*s.* raised by farthings among the children of a County Council school in one of the poorest districts of London." The total sum subscribed will be handed intact to the Governors of Guy's Hospital, an institution, as our readers know, with which Sir Alfred was closely associated as a student, surgeon, and governor for over 40 years.

VITAMIN DEFICIENCY AND ANÆMIA OF PREGNANCY IN INDIA.

AN anæmia of pregnancy is common in India among all communities except the European. The blood picture closely resembles that of pernicious anæmia, and treatment with liver extract is often successful. If untreated the disease is frequently fatal or there may be recovery after delivery. The anæmia is differentiated from true pernicious anæmia by this occurrence of spontaneous recovery and by the rarity of achlorhydria, regarded as an invariable concomitant of true pernicious anæmia. The condition has received a good deal of attention without any light being thrown upon its ætiology so far. A new study, however, has been made by L. Wills and M. M. Mehta, working under the auspices of the Indian Research Fund Association for the Maternal Mortality Inquiry, and they offer some interesting suggestions in the course of a preliminary report.[1] Their first important contribution is the recognition that the disease is not essentially an anæmia of pregnancy, but widely affects women throughout the population. It is only exacerbated by the exigency of pregnancy. Hearsay evidence is quoted that it is even common also among men. The wide prevalence of the condition and the equally wide prevalence of poor nourishment, deficient both in quantity and quality, readily suggest the likelihood that an association between the two is of fundamental importance in ætiology. The report is only a preliminary one, chiefly occupied with the accurate definition of the clinical entity; the dietary evidence is, therefore, not given, but the low content in both vitamins A and C of the majority of the diets is pointed out and is deemed to be significant. Apparently, none of the classical symptoms of vitamin A deficiency or of scurvy is observed, and the deficiencies, therefore, must belong to the latent type, whose importance is being only slowly recognised, probably because prevention or cure by the specific vitamin affords the only means of clinching the diagnosis.

ELEMENTARY KNOWLEDGE OF MALARIA.

THE main facts about malaria can hardly be too generally known among laymen, and a second edition of a pamphlet taken from Sir Ronald Ross's book on the "Prevention of Malaria" is accordingly welcome.[1] It is simply and clearly written and deals first with the parasites, the fever, and the way in which its varying periodicity is produced, and the main complications to which it may give rise. In referring among these to miscarriage, it is stated that while malaria may cause this quinine will not. It does not, however, appear advisable to seem to suggest that a pregnant woman should take quinine, except under medical supervision, unless this is not available. The description given of the mosquito cycle and of the mode of infection of man will be readily understood by one without medical training, though another edition might make it clearer that human and bird malaria are different and are not both carried by anopheles. The general importance of the house as the ordinary place where infection is acquired is emphasised, and it is advised that there should be reluctance to occupy an infected house without fumigation. The means of effecting this are carefully described as well as other methods of personal protection from mosquito bites. The life-history of these insects in its bearing on the transmission of malaria is adequately sketched, as well as the data by which culex, aëdes, and anopheles can ordinarily be recognised in their different stages. The avoidance by the householder of the careless provision of anopheline breeding places receives due attention. Under public prevention, it is pointed out that malaria probably causes a quarter or more of the sickness in the tropics and that the cost of public works for its suppression is likely to be more than recouped by saving in life, labour, invaliding, medical attendance, and hospital accommodation; and that a campaign which effects this will remove mosquito-borne diseases other than malaria, and will improve general sanitation.

BLEEDING AND THIRST.

IT is the custom in most hospitals to press upon a donor from whom blood has been taken a large cup of tea; in a minority of institutions beer is offered as an option; in some plain water only is provided. Except when faintness comes on in the course of withdrawal of blood donors seldom complain of thirst, but it seems only reasonable to provide as soon as possible fluid to take the place of that lost. There is a widespread idea that hæmorrhage gives rise to thirst and that this feeling is a teleological phenomenon designed to induce the organism to make up for the lost fluid. Probably a good many donors thankfully accept the proffered fluid because they feel that after losing a pint or so of blood they ought to be thirsty. Working with animals on whom such considerations can have no effect two French investigators[2] have been unable to find evidence that extensive hæmorrhage gives rise to any particular feeling of thirst. The animals used were horses which in the course of routine work in the preparation of therapeutic sera were bled to the extent of six litres daily for a variable number of days. They were watered in the morning before and in the evening after the withdrawal of blood. On averaging the results of observation of the fluid intake of 72 horses it was found that whereas on the days on which they were bled the intake of water was about 25 litres, on the other days it fell below this figure to the extent of only about one litre and a half, and this in spite of the fact that six litres of blood had been withdrawn. There was, moreover, no tendency for any excessive intake of water in the evenings after the bleedings. In one horse which was bled on 11 days, the evening intake of water after the bleedings was consistently less than the morning intake. The thirst following upon hæmorrhage associated with severe traumatism has long been recognised as one of the major terrors of the battlefield, but it seems probable that this thirst is due rather to the fever following upon wound infection than to loss of blood. The reserves of water in the body are by no means confined to the blood, and it would appear that they are so well conserved that it is almost impossible to seriously deplete them by withdrawal of blood to any extent that the organism can stand. In the horses used in the investigation described above no measurement of the urinary excretion of water was made; had this been done it would probably have revealed a considerable diminution following on the bleedings.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 15TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 433 (last week 393); scarlet fever, 2509; diphtheria, 1704; enteric fever, 46; pneumonia, 1730; puerperal fever, 51; puerperal pyrexia, 101; cerebro-spinal fever, 19; acute poliomyelitis, 6; acute polio-encephalitis, 1: encephalitis lethargica, 14; continued fever, 1; dysentery, 6; ophthalmia neonatorum, 127. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on March 18th–19th was as follows:—Small-pox, 687 under treatment, 26 under observation (last week 594 and 26 respectively); scarlet fever, 2132; diphtheria, 2712; enteric fever, 18; measles, 1043; whooping-cough, 81; puerperal fever, 32 (plus 4 babies); encephalitis lethargica, 123; poliomyelitis, 1; "other diseases," 28. At St. Margaret's Hospital there were 9 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns including London, there was 1 death from small-pox, 2 (0) from enteric fever, 165 (66) from measles, 14 (6) from scarlet fever, 35 (5) from whooping-cough, 43 (14) from diphtheria, 50 (11) from diarrhœa and enteritis under two years, and 85 (13) from influenza. The figures in parentheses are those for London itself.

The fatal case of small-pox was assigned to Shoreditch (Met. Boro.). Deaths from enteric fever outside London were reported from East Ham and Birmingham. Fatal cases of measles were concentrated at Manchester, 12; Sheffield, 10; West Ham and Portsmouth, each 8. (Glasgow also reported 23 deaths.) Whooping-cough claimed 3 victims each at Birmingham and Liverpool. Four deaths from diphtheria were reported at Liverpool, 3 each at Birmingham and Sheffield. The highest figures for deaths attributed to influenza were Portsmouth 5, Birmingham and Manchester each 4.

The number of stillbirths notified during the week was 295 (corresponding to a rate of 42 per 1000 births), including 60 in London.

LONDON HOMŒOPATHIC HOSPITAL.—Last year this hospital, which then completed 80 years' work, received 1712 in-patients; the out-patients' attendances exceeded 56,000. The Hospital Saving Association sent 401 in-patients and 2071 out-patients, for whom £3375 was paid.

LXVI.—THE SIGNIFICANCE AND VALUE OF EXAMINATIONS OF MILK.

PART II.*

Pasteurised Milk.

A MOST important grade of milk is that defined as pasteurised. The term pasteurisation, in connexion with milk, has been used very loosely to apply to all methods of heating milk so long as the temperature does not reach boiling point. Quite commonly it has been applied without qualification to what is called "flash" pasteurisation, by which process milk is heated to a temperature from 160° to 175° F. for a few seconds. This treatment certainly destroys a large proportion of the bacteria in the milk, and therefore improves its keeping qualities, but the treatment does not destroy the most important infecting agent to be found in a certain proportion of the milk supplies—namely, the bacillus of tuberculosis. Besides, unless carried out with care, it somewhat damages the commercial quality of the milk by interfering with the cream-line and by imparting a cooked flavour if the temperature is allowed to get near to 180° F. By the Milk (Special Designations) Order pasteurised milk is specifically required to be retained in a temperature of not less than 145° and not more than 150° F. for at least half an hour, and be immediately cooled to a temperature of not more than 55° F. This method of pasteurisation has been alluded to as the "positive holder" method, because the milk is positively retained for a definite length of time, as distinct from the "flash" method alluded to. In speaking of pasteurised milk and its qualities, it is desirable to use the term in relation to the treatment of milk as thus specifically defined by the Order of the Ministry of Health. When milk is sold as pasteurised it must not contain more than 100,000 live bacteria per c.cm. It need not be bottled, but the vessel in which it is contained must bear a suitable label with the words "pasteurised milk." Although not sold as such, over 80 per cent. of the milk sold in the Metropolitan area of London is pasteurised. A large proportion of the milk sold in the large provincial towns is also similarly treated.

It has been shown conclusively that when milk has been pasteurised by the method as defined, there is an almost complete security against infection from the tubercle bacillus, in fact, the security is as great as, if not greater than, with Certified or Grade A (T.T.) milk. At the same time there is a protection from other pathogenic organisms which may gain access.

It has been contended that pasteurisation alters the character of the milk, but while this contention might be applied to milk treated by the "flash" method, it does not apply to the method defined by the Order. By the latter method the chemical changes are negligible, and the only vitamin that may be reduced is the antiscorbutic or C-vitamin. The amount of this vitamin in milk is very small, however, and its loss can be readily met by the administration of a small amount of orange juice to young children who may have to subsist almost entirely on pasteurised milk.

Grade A Pasteurised.—The only other grade of milk included in the Milk (Special Designations) Order is Grade A pasteurised, which is Grade A or Grade A (T.T.) milk which has been submitted to pasteurisation and which, after treatment, must not contain more than 30,000 bacteria per c.cm., and should have no coliform bacteria in 1/10 c.cm. This is a grade which is really not required. The chief quality of Grade A milk surely is dependent on its raw character, and after pasteurisation there is little to choose between Grade A pasteurised and pasteurised milk.

All these grades of milk, their production and sale, are kept under close supervision by the Ministry of Health and the local authorities named in the Order. There is, therefore, a real guarantee that they comply with the requirements set out. The medical officer of health can always be depended upon to give information to medical men regarding graded milk and regarding the particular quality of any milk supplied in his district.

Milk-borne Infection.

As is well known, many serious outbreaks of infectious disease, such as typhoid fever, diphtheria, and scarlet fever, and of sore-throat have been recorded as having been caused by milk. The recent occurrence of many cases of illness at Brighton is a striking example of milk infection. Their milk-borne character, however, is proved, not by the discovery in the milk of infective organisms, but by the incidence of the cases and by the special features of the outbreak. The evidence in the very few cases in which the bacteria of typhoid fever and diphtheria have been reported to have been found in milk is not conclusive. When one considers the numerous bacteria commonly found in milk and the small amount of infection that may gain admission, the difficulty of isolating the specific infecting agent can be imagined.

The search for pathogenic organisms in market milk is complicated by the fact that many types of organisms are encountered in making a bacteriological examination. Over 160 different organisms have been isolated from milk and identified by cultural and other characteristics. Even the members of the coliform group are numerous. Contrary to the popular view, milk drawn from the udder with aseptic precautions is not sterile, but contains a varying number of bacteria, being greatest in the fore-milk, in which there may be thousands, and smallest in the strippings, in which there may only be three or four per c.cm. The bacteria obtained from the inside of the normal udder are coccal in form. Where there is mastitis streptococci may appear in large numbers. To isolate the streptococcus of mastitis or Bang's bacillus of contagious abortion from milk directly drawn from the udder of an affected animal is a comparatively easy matter. In the course of ordinary milking operations many forms of bacteria are added from the air, from dirt or fæces falling from the outside of the udder, and from the milk vessels. It is from the particles of fæces and from the imperfectly sterilised milk vessels that the coliform bacilli are usually added. During transport from the cowshed to the consumer the milk receives varied additions of bacteria unless careful precautions are taken to exclude contamination by the use of sealed bottles or proper churns.

The recognition during recent years, in different countries, of cases of undulant fever associated with the consumption of milk has evoked much interest. Although Bang's bacillus has not been isolated from the incriminated market milk, there can be no doubt after weighing all the evidence in individual cases, regarding its bovine origin and its pathogenic influence in causing fever in the human subject.

Milk-borne Tuberculosis.

The most important milk-borne disease undoubtedly is tuberculosis, and therefore it deserves most consideration. It is difficult to state with any degree of accuracy what percentage of cases of tuberculosis is of bovine origin, but the following table, compiled by

---

* Part I. appeared last week.

Dr. A. S. Griffith, represents results obtained by him up to the end of 1927 :—

Cases of tuberculosis.	Children—				Persons 15 years and over.	
	under 5 years.		5–15 years.			
	H.	B.	H.	B.	H.	B.
1280	167	114	442	167	379	25

H. = human ; B. = bovine.

Bovine tuberculosis thus forms a much large proportion of the tuberculosis found in children unde 5 years of age than in those between 5–15 years, while in persons 15 years and over the percentage of the bovine type of infection is very small. These are significant figures, indicating as they do the greater prevalence of the bovine type of tubercle amongst those members of the community who consume most milk. Somewhat similar figures have been put forward by other observers. Taking all the evidence relating to bovine infection of the human subject, Dr. W. G. Savage, in his book, "The Prevention of Human Tuberculosis of Bovine Origin," states :—

> "The position can be summed up by saying that, while the tubercle bacillus of bovine origin is probably not responsible for more than about 5 per cent. of the total tuberculosis mortality, yet this proportion is considerable, and its continuance is not creditable to our public health administration."

The percentage of milk supplies infected with tubercle bacilli varies greatly in different towns, but it may be accepted that the average is about 6·5 per cent. This figure relates to unselected samples of milk as delivered at the town and not treated by any heating or pasteurising process. The number of cows with tuberculosis of the udder used to be estimated by competent observers as about 2 per cent., but Savage, as a result of recent figures, has shown that the percentage with clinically detectable tuberculosis of the udder in unselected herds is about 0·2 to 0·3.

The detection of the tubercle bacillus in milk is not an easy matter. Methods have been suggested at various times by which the tubercle bacilli can be detected by microscopic examination. In these methods some form of concentration or centrifugalisation of the bacteria in the milk has predominated, followed by the making and staining of films made from the deposit. With the Ziehl-Neelsen stain the appearance of the tubercle bacillus is quite characteristic under the microscope. But these methods have proved untrustworthy, and the only process that can be depended upon is by the injection of the suspected milk into guinea-pigs. This is carried out by centrifugalising about 10 to 40 c.cm. of milk and then injecting the deposit subcutaneously into the inner side of the thigh of a guinea-pig. Three weeks must elapse before the guinea-pig is killed and examined for evidence of tuberculosis. The great drawback is that if the milk is infected, much damage can be done in the meantime to young persons ingesting it owing to the delay in completing the examination.

The health authorities of most large towns regularly take samples of milk to be tested by animal inoculation for the presence of tubercle bacilli. Infected supplies produced within the area of a county borough are investigated by the county borough council, and steps are taken to discover the offending animal and have it destroyed ; those produced elsewhere are reported to the council of the county in which the farm is situated and similar action is taken, the results of which are reported to the council of the district where the infected milk is being sold.

Under the Tuberculosis Orders the farmer is supposed to notify any cow which is, or appears to be, suffering from tuberculosis of the udder or from indurated or other chronic disease of the udder, but before this condition is recognised by the farmer there may have been much damage done, since the affection may only be recognisable by him when it is in an advanced condition. Regular examinations of milking herds by veterinary inspectors, as carried out in some counties, is therefore called for as a first step in the early detection of infective animals and in the elimination of tuberculosis from the dairy herds of the country. This would bring about the disappearance of all the most active cases of the disease, and if this procedure were followed by the tuberculin testing of all stock, a good deal of progress could be made in getting tuberculosis-free herds. A comprehensive and bold scheme is urgently needed.

THOMAS ORR, M.D., D.Sc.,
Medical Officer of Health and School Medical Officer, Ealing.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. B. R. Bickford is placed on the retd. list, with rank of Surg. Capt.

Surg. Lts. (D) to be Surg. Lt.-Comdrs. (D) : O. J. Barrable, E. R. Longhurst, H. N. V. Barnes, D. H. le Marchant, and D. L. Simpson.

The following appointments are notified : Surg. Comdrs. H. L. Douglas to Royal Naval Hospital, Yarmouth, and A. T. Rivers to *President*.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. J. S. Gallie, late R.A.M.C., having attained the age for compulsory retirement, is placed on retd. pay.

Col. J. A. Hartigan, late R.A.M.C., to be Maj.-Gen., vice Maj.-Gen. J. S. Gallie, to retd. pay.

Lt.-Col. E. W. Powell, from R.A.M.C., to be Col., vice Col. J. A. Hartigan.

Col. O. M. Harris, on ceasing to be empld., is placed on half pay.

Lt.-Col. E. M. Pennefather retires on retd. pay.

Temp. Lt.-Col. C. F. White to be Lt.-Col., vice Lt.-Col. E. M. Pennefather.

Temp. Lt.-Col. F. C. Sampson to be Lt.-Col., vice Lt.-Col. E. W. Powell.

Majs. H. E. Priestley and J. S. Dunne to be temp. Lt.-Cols.

Maj. R. B. Price, from the secd. list, is restd. to the estabt.

Lt. W. F. L. Hannay resigns his commn.

TERRITORIAL ARMY.

Lt. W. L. Lamb (from T.A. Res. of Off., R.A.M.C.) to be Lt.

Lt. M. R. Coolican to be Capt.

D. G. Robinson to be Lt.

ROYAL AIR FORCE.

Group Capt. H. Cooper is appointed Honorary Surgeon to the King.

Air Vice-Marshal David Munro relinquishes his appointment as Honorary Surgeon to the King on retirement from the Royal Air Force.

Flight Lt. J. F. McGovern is granted a permanent commission in this rank.

INDIAN MEDICAL SERVICE.

Majs. to be Lt.-Cols. : F. J. Kolapore, E. G. Kennedy, J. V. Macdonald, H. A. H. Robson, C. G. Howlett, C. Newton-Davis, R. C. Clifford, C. Newcomb, H. E. Shortt; T. A. Hughes, H. L. Batra, D. McN. Taylor, and W. O. Walker.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

The annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 2.30 P.M. on Friday, April 11th, at 11, Chandos-street, Cavendish-square, W. 1, when the annual report and financial statement for the year ended Dec. 31st, 1929, will be presented, and the officers and committee for the current year elected.

THE Food Education Society (29, Gordon-square, London, W.C. 1) has issued a leaflet entitled Bread and Its Place in Diet. This is obtainable for 1½d., post free.

CROTCH v. MILES.

ACTION FOR ALLEGED NEGLIGENCE IN THE KING'S BENCH DIVISION.

THE hearing of this case before the Lord Chief Justice and a special jury was continued on Tuesday morning, March 18th.

Mrs. MARTHA HARRIET GORDON CROTCH, of "Auntie's Tea Shop," Place Peyra, Vence, near Nice, alleged that Mr. WILLIAM ERNEST MILES, of 14, Park-crescent, W. 1, after performing on her the operation of sub-total hysterectomy for a large fibroid tumour, *left in the abdomen a pair of* 6-inch Spencer-Wells forceps, which were only discovered at an X ray examination made eight years afterwards. The Defendant denied that he left the forceps in her body, or that they were left in through any negligence or want of skill on his part or on that of any person for whom he was responsible. He also pleaded that the claim was barred by the Statute of Limitations, 1623.

MR. MILES'S EVIDENCE—(*continued*).

Questioned by Mr. RAYNER GODDARD, K.C., Mr. Miles said that four of five years ago he had replaced all his instruments by similar ones made of stainless steel. His housekeeper, Miss Doris Ruddock, had placed the old ones in a cardboard box—as they were condemned instruments—and they had been there ever since. He produced the six pairs of Spencer-Wells forceps which he had used in the operation on Mrs. Crotch. They were, he said, marked S I H; the S was near the screw, the I below it, and the H below that. The letters stood for the Holborn Surgical Instrument Company. He had bought these six pairs of forceps from the makers in—as far as he could recollect—1899 or 1900, since when they had been in constant use until he has discarded them for stainless steel ones. Asked to inspect the pair that had been extracted from the body of Mrs. Crotch, he said that it bore an H about a quarter of an inch below the screw, and about a quarter of an inch from the exact position where the S was on one of the forceps he had produced. The letters S I H appeared in the same order on each of his six pairs.

The forceps in question, with a pair of those produced by Mr. Miles, were handed to the jury.

Every surgeon, said Mr. Miles, used Spencer-Wells forceps, which were made in two sizes. Replying to Mr. Rayner Goddard, he said that he had served in the war for nearly five years. Thousands of Spencer-Wells forceps had been used in France during the war.

Mr. RAYNER GODDARD: Assuming that these forceps had been left in a person's intestine for eight years; is the state of corrosion such as you would expect after eight years' loss?—On looking at these forceps I see plating, and I cannot conceive that a pair of forceps would remain for any length of time and the plating be still there. I can produce a witness.

We will produce a witness with actual experience. Do you think that the plating could be visible on the forceps after eight years?—I should not say so, although I have no actual experience.

THE LORD CHIEF JUSTICE. What is the ordinary purpose for which an instrument like this forceps is used?—For picking up small vessels. When you have made an incision, and a small artery or vein or even a larger artery is squirting, it is nipped with the point of the forceps, so, and tied off. I do the tying except when it is rather awkward. If it is awkward my assistant holds the forceps and I tie, after which he takes the forceps off. If it is more convenient for him to tie, he ties and I take them off.

To a person who is not a surgeon an instrument like that looks like a pair of scissors, and a pair of scissors is an instrument with which you cut and which you then put aside. Those instruments, as I understand it, are used to be put in position and to remain in position?—No, if your Lordship means that they remain indefinitely.

No, to remain in an appreciable time to prevent bleeding—They could remain there until you occluded the vessel by a ligature.

You apply the forceps and leave it to stay the bleeding at the bleeding point?—Precisely.

Cross-examined by MR. J. W. MORRIS.

As soon as these forceps arrived in this country after they had been extracted from Mrs. Crotch's body, you had every opportunity of examining them?—I had.

I think you first had an opportunity of examining them about a year ago or more?—Yes; somewhere about that.

These forceps are undoubtedly Spencer-Wells forceps?—Without doubt.

And without doubt they are 5-inch Spencer-Wells forceps?—I agree.

And without doubt they are forceps which have a screw?—Yes.

That is quite a distinct kind from the kind in which the two limbs are detachable?—Yes.

When you first saw the forceps you saw on them the letter H?—No, I did not.

When did you first see the letter H on them?—I saw it when I went down with Mr. Hempson to the Plaintiff's solicitors; there was one of the assistants of the Holborn Surgical Instrument Company there, and he scraped the forceps—with their permission—and then I saw it. That was the second time, and not so very long ago.

You do not for a moment deny that those forceps are of the type you used in 1920?—Certainly; they are of that type.

Are those forceps that were extracted your forceps?—I have no means of identifying them or of saying whether they are.

You cannot deny on your oath that those are your forceps?—These forceps have an H on them. I have no forceps that have an H on them only.

Do you prefer not to answer the question, Mr. Miles? You cannot deny on oath, can you, that those are your forceps?—I think I can.

Did you use those forceps in the operation on Mrs. Crotch in 1920?—I cannot possibly say, because I do not know.

Did you leave those forceps in Mrs. Crotch's body after the operation?—I do not know.

Do I understand that the forceps which you have produced this morning, and a pair of which you have there, were bought in 1899?—In 1899 or 1900, I should imagine.

When did you buy this particular one which I have in my hand?—I do not know which one of the six you have.

Were they bought at different times then?—I bought twelve forceps somewhere about that time.

But I have in my hand one of the six you referred to this morning?—Yes.

You say you bought twelve; when?—Somewhere about 1899, 1900, or may be 1901; I do not know.

You bought them from whom?—The Holborn Surgical Instrument Company.

What was the next occasion when you bought some 5-inch Spencer-Wells?—I never got any more 5-inch Spencer-Wells forceps.

Until the time you told us of this morning?—I bought in 1896 twelve pressure forceps from Arnold's; they were detachable forceps. I bought these six from the Holborn Surgical Instrument Company.

What do the letters "H I S," in that order, stand for?—I suppose the Holborn Surgical Instrument Company.

THE LORD CHIEF JUSTICE: At the time of the operation, how many of these instruments had you in your possession?—I had about twelve small pressure forceps.

All Spencer-Wells?—They were Spencer-Wells.

Of those twelve, I understand that you have produced six?—These six were in my special abdominal bag.

Where were the other six ?—I have got them.

You have got all twelve ?—Yes, but the others are not all by the Holborn Surgical Instrument Company. When I was serving in France, commanding No. 7 Red Cross Hospital, I used some of my own instruments. I handed them into the Quartermaster's stores, and when the hospital disbanded, I received six instruments in return, but any six that they produced ; some were Allen and Hanburys, some Arnold's.

But when you say that on Nov. 27th, 1920, you had twelve small pressure forceps, do you mean that they were twelve which you yourself had got from the Holborn Surgical Instrument Company ?—No, my Lord, I did not say that they came from the Holborn Surgical Instrument Company, because I bought twelve and took six out with me to France in 1914.

Are you in a position to say how many small pressure forceps of the Spencer-Wells type which you yourself had bought from the Holborn Surgical Instrument Company you had in your possession on Nov. 27th, 1920 ?—I had got these six, and I have got two which are unmarked, but which seemed to be Holborn Surgical Instrument Company's forceps, but there is no mark on them ; that is possibly because they were replated.

Mr. MORRIS. In answer to my Lord as to the number of forceps you had on Nov. 27th, 1920, you said "I had about twelve pressure forceps."—Yes.

Can you tell us precisely how many you had ?—I have got twelve now.

That is not the question, Mr. Miles. You were asked by my Lord how many pressure forceps you had on Nov. 27th, 1920, the date of this operation, and you made answer "I had about twelve."—Well, there are twelve.

How many precisely did you have ?—Twelve.

Why did you say "about twelve"?—That may have been just an expression. I say now : "twelve."

Did you tell us that you were accustomed to great precision in these matters because you deal in multiples of three ? Why did you say to my Lord "about twelve"?—What I probably should have said was "twelve."

I understand that you told my Lord in answer to a question that you have other forceps besides these six brought here this morning.

THE LORD CHIEF JUSTICE. You say—I may have misunderstood or misheard you—but I understood you to say : "Four or five years ago I substituted stainless steel instruments for those I was using ; I put the abdominal instruments into a special abdominal case, and Miss Ruddock put the old ones away in a cardboard box. I produce the instruments I was using at the time of the operation on the plaintiff, all six of them."—All six, together with the other ones of different types.

Are you in a position to account for and to produce all the surgical instruments of this nature—the Spencer-Wells forceps—which you had in November, 1920 ?—Yes.

At any rate they are not here ?—I have only got the six.

Mr. MORRIS. I understand, Mr. Miles, you referred to two others which you mentioned specifically. What were those two ?—The two that have no mark on them, but are identical in shape and form with those forceps, and the probabilities are that the lettering was obliterated when they were replated. Miss Ruddock will tell you that I used to send my instruments to be replated when necessary.

Where were those two bought ?—They were probably bought from the Holborn Surgical Instrument Company.

Probably ?—Because they have no mark on them I cannot say.

Where did you get them replated ?—At the Holborn Surgical Instrument Company.

And when they are replated, is the whole of the first plating taken off ?—I could not tell you. I do not know what process they use.

Do they come back with no mark on them ?—I could not tell you that.

How often do you send them to be replated ?—An instrument may last several years, and sometimes the plating will chip off the first time you use it. That is why I have stainless steel.

How long does it take to replate ?—I do not know.

But you know how long they were away from you ?—I generally send them away when I am on my holiday. That is a convenient time.

Mr. Miles stated that he had never bought forceps from either Allen and Hanburys or Arnold's.

Mr. MORRIS. What do the letters H I and S in that order mean ?—I cannot tell you. Holborn Surgical Instrument Company ?

That would be H S I, wouldn't it ?—I do not know ; I am not responsible for putting those letters on the instrument.

What does the letter H stand for ?—I should imagine, Holborn.

Was that forceps in front of you which was extracted from Mrs. Crotch's body made by the Holborn Surgical Instrument Company ?—Apparently, because it has got an H on it.

The company from whom you bought your instruments ?—Yes, but when I bought mine they did not mark them with an H only.

Have these in my hand been replated ?—I could not tell you.

Have the six you referred to this morning been replated ?—I could not possibly tell you.

Have you any records of dates when you bought these instruments and sent instruments to be replated ?—No, I cannot possibly remember, but I know that I bought these instruments early in my career and I have been practising for thirty years.

Mr. Morris put further questions about the instruments which Mr. Miles had taken to the war and those he had brought back ; Mr. Miles admitted that he could not remember exactly how many Spencer-Wells forceps he had taken out to the war, but he knew that he had left six Holborn Surgical Instrument Company forceps behind in his abdominal bag. No stock or inventory had ever been taken of his instruments.

Mr. MORRIS. You have heard, have you not, of the precise spot from which the forceps were extracted by the French doctors ?—Yes.

And you have seen the X ray photographs ?—Yes.

Were the forceps underneath the place where you operated in 1920 ?—I do not understand that question. I saw the place where the French surgeon marked on the diagram (an instructional model, put into Court) the spot from which he said he had removed those forceps. I say that he drew them longitudinally in the middle line ; those forceps were shown not to be longitudinal in the middle line by the X ray, and the X rays do not lie.

Mr. Miles then identified the anatomical parts on a similar model.

Mr. MORRIS. There is no doubt, is there, that the operation for the removal of the gall-bladder is one that entails an incision above the umbilicus ?—Yes.

And that for your operation of sub-total hysterectomy your incision was below the umbilicus ?—Yes, what we call a sub-umbilical laparotomy incision.

And your incision was down the median-line ?—Absolutely in the middle line from the umbilicus to the symphysis pubis.

Is the place where these forceps are marked in ink on this model approximately underneath the line of your incision ?—In the place where he has put them, it would be, but that is not where they are shown in the X ray.

THE LORD CHIEF JUSTICE. You heard the evidence read on the last day—it was taken in France—and you know what was said of the place where the forceps was found in the body ?—It was in the "*petit bassin*," I think, my Lord.

Suppose that that forceps had been used for th purposes of the operation of removing the gall-bl the incision for that purpose having been made i ordinary place for that purpose and that the had then by inadvertence been left in : was it p possible for the instrument to travel down where it was shown?—I think so, by the force of gravity. Moreover, there is another point. Supposing that a pair of forceps had been left in in that position and had descended by the force of gravity, the greatest resistance to the descent would be offered by the rings. The position shown in the X ray is perfectly consistent, in my opinion, with their having travelled down.

Mr. MORRIS. For how long after an operation for removal of the gall-bladder would a patient be flat on her back?—It depends upon the surgeon. I generally like to keep my patients in bed for three weeks after a big abdominal operation.

So that the force of gravity would be for three weeks a force quite different from the direction that you were indicating?—Possibly, but then I do not know that this patient was not put in a sitting-up position.

THE LORD CHIEF JUSTICE. You say that the drawing of the forceps is incorrect and does not tally with the X ray photograph?—That is precisely my contention, my Lord.

Assume that the X ray photograph correct and suppose that that forceps had by inadvertence been left in the Plaintiff's body at the time when you performed your operation in 1920; could the instrument afterwards have been found in the place shown by the X ray photograph?—I do not think so, because my operation was entirely confined to the true pelvis, which the French call *le petit bassin*.

Mr. Miles then gave a detailed anatomical description of the pelvis. He concluded—So if the round ligament had gone through the ring of the forceps, they would have been found at the level of the ilio-pectineal eminence instead of where they are shown in the X ray picture.

He then pointed out the discrepancy between the French surgeon's mark on the diagram representing the position of the forceps as estimated by him, and their position as shown by the radiogram.

Mr. Morris read the following questions from the evidence of the French practitioner, Dr. D. Maestracci:

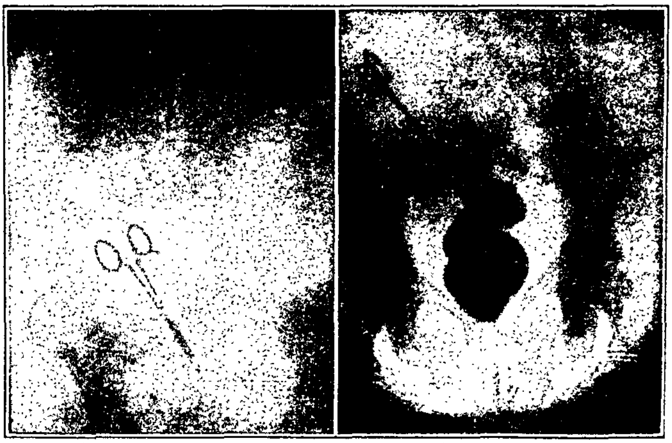
> Look at the two X ray photographs B and C; where do they show the forceps to be?—Inside the small pelvis on the right hand side.
>
> Where were the forceps with reference to the external laparotomy section?—On the right half of the scar, underneath.

Mr. MILES. That is anatomically wrong.

Mr. MORRIS. Do you dissent from either of those answers?—Absolutely, they are anatomically wrong. The man was talking nonsense. This is the small pelvis, further down; they would have been here (indicating a point several inches higher). Anatomically, he is talking absolute rubbish.

THE LORD CHIEF JUSTICE. The *petit bassin* is what you call the little pelvis?—Yes; the true pelvis in English anatomy. He says they are in the true pelvis, and he is wrong.

You mean that the X ray shows they were there (*indicating a higher point*)?—Yes; I have no other evidence. The X ray shows they were there, and the X ray shows their relation to the skeleton.



The two X ray photographs marked "B" and "C" in the depositions of witnesses examined at Nice and admitted in evidence during the hearing of the case *Crotch* v. *Miles*. They bear the legends:—(1) Mrs. Crotch: Radiographie de l'abdomen avant le lavement baryté (20.9.28); (2) Rapports du corps étranger avec la portion terminale du gros intestin (20.9.28). The interrupted line on the left-hand radiogram indicates the position of the incision made by Dr. Prat at the operation for the removal of the gall-bladder (see THE LANCET, March 22nd, p. 649).

Mr. MORRIS. You do not dispute that the forceps were found either inside the small intestine or in the folds of the small intestine?—I did not see them and did not take them out. I do not think they were in the small intestine.

You have no reason to doubt that they were at least in the folds of the small intestine?—Yes, they were in between the coils; I admit that.

THE LORD CHIEF JUSTICE. In between the coils but outside?—Yes, I am perfectly certain of that. (The witness illustrated how two surfaces of the peritoneum covering the small intestine might form an adhesion through a ring of the forceps. It was impossible, he said, that an adhesion could ever form between two parts of the mucosa lining the small intestine.)

Mr. MORRIS. Is it not a fact that bodies may work their way into the small intestine itself?—It has been known; I have known, for instance, of a swab ulcerating its way in.

How do you account for the presence of fæcal matter on those forceps?—I am not at all certain that it is fæcal matter. I should say it was an incrustation.

Supposing the French surgeons are right in saying that it is fæcal matter; how do you account for it?—If it is fæcal matter, probably the point of the forceps may have just perforated the bowel; that is just possible, but if it had been so, this patient would have contracted a very acute abscess with leakage, and the contents of the bowel would have been free to enter the abdominal cavity. When the forceps were removed, there would have been an enormous abscess cavity. That is why I do not think for a moment that the forceps were ever inside the intestine.

You have read the evidence of the French surgeon?—Yes, but that has no weight with me at all. I judge things on my own knowledge; I do not take anything that a Frenchman says or anyone else.

Do eminent medical men have differences of opinion when each thinks that the other is wrong?—Yes, but not on a question of anatomy.

You know that it is the view of French surgeons that forceps with a screw are not so sanitary as dismountable forceps?—Absolute nonsense of the worst type. It is easier to clean detachable forceps mechanically, but not to sterilise them. French surgeons can do what they like.

And British surgeons use screw forceps and not dismountable ones?—Certainly.

I understood you to say on Friday that the presence of forceps amongst the intestines would cause a swelling?—Naturally. You could not put that pair of forceps among intestines without it.

And the swelling caused by those forceps would cause the muscles or other covering to swell out?—Not the muscles. You would feel a tumour under them.

It would cause the muscles to bulge?—That is right.

If the muscles were bulging, would they bulge through the point in the abdominal wall where there was weakness?—Not necessarily, by any means.

Supposing an incision had been made in the abdominal wall, the line of that incision would not be as strong as the remainder of the wall ?—Very often much stronger, but in stout people, especially after a strong fit of coughing, some of the stitches may break away, or the wound may bulge a bit. Ventral hernia is therefore quite a common thing. No ventral hernia, however, is produced by a foreign body unless it has been driven through the abdominal wall as by shrapnel in the war.

Does the ventral hernia take place at some point on the line of the incision ?—Yes.

If you were explaining that to a layman, would a reasonable explanation be that the muscles had been displaced by the operation ?—No, I do not think so. I should say that the scar would have stretched.

If there were some swelling or foreign body which caused pressing, it would press one way towards the urinary bladder and the other way towards the rectum ?—If the foreign body were down in the pelvis it would, because the two organs are close together, but in this case it was not in the pelvis.

And if one of the symptoms in this case were urinary trouble—incontinence—might that have been caused by the presence of a foreign body ?—Not necessarily, because cystitis is a common thing, and you very often get coli bacilluria.

Might it have been so caused ?—I do not see how it could have been, unless the foreign body were absolutely pressing into the bladder.

And supposing it was absolutely pressing into the rectum ; might there be what one French surgeon has called tenesmus ?—Tenesmus is simple contraction caused by any irritating condition, such as colitis or rectitis.

Might it cause the trouble in defæcation ?—If you had a pair of forceps pressing on the rectum, of course it would, but the X rays show that they were not there.

Mr. Miles, in answer to a question, explained the anatomy of the abdominal viscera. In reply to the Lord Chief Justice, he said that in neither of the two operations was it ever necessary to open the intestine.

MR. MORRIS. You do not suggest, do you, that the leaving of a pair of forceps in a patient's body can in no case be due to the surgeon's negligence ?—I do not say it is due to negligence ; I say this : that one takes every possible care to prevent such a thing, because no one would willingly leave a pair of forceps in anyone's abdomen.

That is not quite an answer to the question. You do not suggest, do you, that, in any case in which a forceps is left in the patient's body, it is not due to negligence by the surgeon ?—I cannot conceive of negligence, because every endeavour is taken to remove any forceps that you use if you do put them in there. It may be accidental, but that is not negligence.

It may be that the leaving in of a pair of forceps in a given case is the grossest negligence ?—You can conceive that, but I do not consider that I have ever been negligent.

Might not the presence of a pair of forceps in the peritoneal cavity cause the gravest consequences, such as a complete puncture of the intestine ?—Certainly.

Might that cause fistula and death ?—I do not know about fistula, but it might cause an abscess.

It might cause peritonitis ?—If it were septic, yes.

You will agree with me that a surgeon ought to do everything that is humanly possible to avoid such grave consequences ?—Certainly and absolutely.

And that, if the surgeon counts his instruments before an operation, and again when the operation is over, he has an infallible test ?—As near as you can humanly make it.

It is an infallible test if he only uses six Spencer-Wells forceps and has six before and six after ?—Yes.

I gather that in your practice you count them yourself ?—I always count my instruments when I take them and hand them over to the sister, and I always count them afterwards.

So, if these were your forceps, your system broke down ?—Yes, but I deny that these are my forceps.

You will agree that the removal of all instruments is a vital part of the operation and that if a surgeon leaves forceps in a body he has not finished his operation properly ?—Yes, but in an operation you are not dealing with a motor-car, where you can smoke your pipe and think about it. You must take your sister's word that the instruments are right. There is no getting away from that.

It is the practice of surgeons to keep a careful note of the details of an operation ?—No, never particular details.

Have you got any notes of this operation ?—No. I think that I must have made notes about it, but I have looked for them and cannot find them anywhere, though I have several notes of about the same date.

THE LORD CHIEF JUSTICE. This is one of the difficulties of trying a matter which is ten years old.

MR. MORRIS. Do not surgeons in fact keep their notes for anything up to twenty years ?—Yes, I could show you notes that I took in 1898 or 1899, but the notes of this case must have got lost when I moved.

Were there not other tumours which you had to remove in this case ?—No, but there was some inflammation of the left Fallopian tube and ovary; there were a great many adhesions which were evidence of a pre-existing peritonitis.

Did other medical men come to see the particular matters that had been removed from Mrs. Crotch ?—Only Dr. Wadd and Dr. Burn.

How many people were present at this operation ?—I cannot be quite certain, but Dr. Wadd assisted me, Dr. Burn gave the anæsthetic, and there was a theatre sister and, I believe, one other nurse.

Mr. Miles said he thought he had operated in a room fitted out as a theatre for the occasion. He had not known the name of the theatre sister or whether she was regularly employed by Dr. Wadd or not. In reply to the Lord Chief Justice, he said he thought he had worked with her before, as he had previously operated at the Hydro three or four times.

MR. MORRIS. You stated in your evidence in chief that you thought the theatre sister was competent ; on what did you base that answer ?—Dr. Wadd would say she was competent and would know she was competent, and as far as I can recollect she had been present at operations before. Moreover, it is generally possible to tell whether anyone is competent or not by the way in which they set about things.

When an operation starts you are in supreme control of everybody in the room ?—I am in control, yes. I do not interfere with people.

Are you in supreme control ?—I control them, but I cannot prevent them from saying and doing what they like. They are under my direction, but I do not understand the words "supreme control," because I cannot control anyone.

Is it within your power to tell a nurse to do a certain thing ?—Yes, I can ask her, certainly.

Can you tell her how she is to do a certain thing ?—I could, but I do not.

Supposing a nurse acted improperly during an operation, you have the power to turn her out of the room ?—Yes, I should object to her, certainly.

Is the credit for a successful operation not attributed to the surgeon ?—It generally is, but all the team get their due.

Mr. Morris read the passage from the judgment in Hillyer *v.* The Governors of St. Bartholomew's Hospital (2KB. 1909. 826) which deals with the responsibility of the surgeon for the actions of his assistants at an operation, and which held that they are under the sole orders of the surgeon. Mr. Miles concurred that this ruling conformed with sound surgical practice and agreed with the phrase "the surgeon is, for the time being, supreme."

THE LORD CHIEF JUSTICE. Of course the question there, Mr. Morris, was whether the governors of the hospital were liable for damages, and it was held that the operation staff were not the servants of the governors. But it does not follow the other way round, that the nurses assisting at the operation are the servants of the surgeon.

Mr. MILES. (To Witness.) I understand from your evidence in chief that you keep a superintendence over what the others are doing in the room?—You cannot look to see everything that the nurse does, but there is an instrument table at your right hand and it is possible to glance here and there. As for the anæsthetist, I can never see what he is doing, and I rely on him to tell me whether the patient is quite well.

How long did this operation take?—In my recollection, an hour or more.

Mr. Miles said that he had done sub-total hysterectomies in 25 minutes, but that this one had been very complicated. He admitted having used 5-inch Spencer-Wells forceps of the type which he had produced, in the first stages before the peritoneum was opened. Asked whether he had gone straight on to another operation, he said that he had not.

Mr. MORRIS. Suppose that during an operation you find that you have not enough instruments of a particular kind, what do you do?—I know what I am going to do and take the number that is necessary.

If a patient is big and stout, there might not be more than six bleeding points?—There might, but if there are you ligature them off and put the forceps on to the vessel you divide at the next cut. You do not divide right through and get all your bleeding at once.

Have you ever had occasion to send for more instruments other than those which you have taken out for the operation?—I do not remember ever having done so, except that in a case in hospital you may suddenly want a special instrument; it is then procured.

Would there be instruments available at the Hydro?—I suppose Dr. Wadd has some, but I always make a point of using my own if possible.

(Mr. Morris questioned Mr. Miles on one of the X ray photographs.)

There is no doubt that the forceps on that photograph are shown as being opened?—No doubt whatsoever.

There is no doubt, is there, that there was never occasion to have forceps in that part of the body lying open?—There was not. What the picture shows was that they were not attached to the bleeding point.

Mr. Miles described the process of screening off the intestines with towels clipped together by Lane's tissue forceps. It would, he said, be impossible to use Spencer-Wells forceps for this purpose.

Mr. MORRIS. I understand that one of the four towels in this particular operation would be below the pubis?—Yes, just across the symphysis pubis.

After you have made your incision and when you have clipped some of the bleeding points with Spencer-Wells, you ligature them off, and take off the Spencer-Wells?—Either I or my assistant does it.

You would put those Spencer-Wells down on one of the towels?—Not necessarily. Sometimes I should if a patient is lying flat. You can put it down there or on the table, and the sister may take it.

According to your evidence, you are going to use Spencer-Wells again in a few moments?—Yes.

And you want them near at hand?—Yes.

It is considered desirable, is it not, to avoid moving instruments about too much for fear of infection?—They must only be touched by people with sterile gloves.

You told us on Friday that an instrument may get lost in a towel?—Sometimes at the completion of an operation you may find that a towel has covered up a pair of scissors or dissecting-forceps.

One of those might slip into the wound when you are taking away the towel?—Oh, no, that is untenable, because one is attending to the process.

In what position was the patient?—Horizontal.

So the towel below the pubis would be quite horizontal to contain instruments which you wanted to put there?—Yes, it is between the thighs.

And I understand that an instrument may get lost in the towel?—It is on the surface; it will not get lost there.

At the end of the operation is it your duty to have a good look round the wound before you sew it up?—Yes, at the field of the operation, but one does not want to rummage round the patient's inside. Surgical technique is, moreover, a ritual, and does not admit of looseness of expression. You say have a "look round." The surgeon is doing something.

What, then, is the appropriate phrase?—A careful search. You have your own eyes and your assistant's and sometimes you would feel as far as you could.

Feel in the wound?—Yes, after a hysterectomy, when you have completed your operation and the wound is still held open by self-retaining retractors, the pelvis is as open to you as the interior of your hat. Part of the ritual of an operation on the abdomen is what we call the toilet of the peritoneum, for ensuring that no raw edges are left, and that everything is tucked away, and small bits of blood-clot removed. The hollow is completely empty.

Suppose that after an operation you discovered that you were one instrument short; what would you do?—If, after a search outside no one could find it?

Yes; if the absence of a forceps was not discovered until you had counted your instruments after the patient had been sewn up, and you had reason to believe that a pair of forceps had been left inside the body. Would it be your duty to inform the patient?—I should certainly take steps to find out if they were there. I should not inform the patient unless I knew that they were there.

You would take an X ray?—Yes, I certainly should.

Questioned about the visit of Mrs. Crotch in 1921, after the operation, Mr. Miles admitted that Mrs. Crotch's recollection was more likely to be accurate than his own.

Mr. MORRIS. Supposing Mrs. Crotch had asked you whether she had another tumour, it would have been correct, would it not, as the uterus had been removed, to say that there was nothing now to which a tumour might adhere?—No, I could not have said that, because she might have had a tumour from another condition.

Mr. GODDARD said that you could not have noticed anything or you would have communicated with Dr. Wadd?—Yes.

I understand that you did communicate with him?—I either telephoned to him or wrote to him.

But you have no recollection what you told him?—No. I probably told him that I had seen Mrs. Crotch, but I have no impression on my mind that she had anything which would lead me to think that she was in trouble.

If Mrs. Crotch had your assurance that that swelling was something that she need not worry about, there was no more that she could do?—I do not agree that I said she had a swelling.

You have heard Mrs. Crotch's evidence that for the whole of the eight years she had what she described as an agonising catch of pain?—Yes.

Is that acute pain consistent with the presence of a pair of forceps in the intestine?—I could not say. I have known many people with foreign bodies in their insides during the war, but I do not recollect any of them, unless they had an abscess, complaining of acute pain.

And her evidence that she had some measure of ease in lying down rather than walking about; is that consistent with the pressure of a pair of forceps?—There are many other things that might produce it. I have no experience of a patient with a pair of forceps inside him, but I have had experience of patients with bits of shrapnel five or six inches long, and have taken them out.

And these other troubles of which she has told us—the urinary incontinence, and so forth—are they consistent with the presence of forceps ?—There again I cannot tell you, because I have had no experience. A patient may have urinary and rectal symptoms from a variety of causes.

But amongst those causes would be the presence of a pair of forceps ?—I do not think so, unless they were absolutely pressing or ulcerating through the bladder or rectum.

Re-examined by MR. RAYNER GODDARD.

Mr. Miles said that forceps lying as shown in the X ray picture would not be pressing against or touching the bladder in any way.

In 1920, where did you keep your spare instruments, if you had any ?—I had a specially made box with three tiers like a suit-case, with one part which I could use as a steriliser.

Mr. Miles said that he had never used Spencer-Wells forceps for fixing towels. He had not performed another operation that day. He took his own nurses when he operated at a strange nursing home, but from his experience of Dr. Wadd's hydro he had not considered it necessary. Dr. Wadd was a very excellent surgeon, and he relied absolutely on his judgment.

MISS DORIS GERTRUDE RUDDOCK.

Examined by MR. RAYNER GODDARD.

Miss Ruddock said that she was housekeeper to Mr. Miles, and that between 1919 and 1924 she had been in charge of all his surgical instruments. He had had two instrument bags, one rectal and one abdominal, and instruments were never transferred from one to another.

MR. GODDARD. What were the instruments placed in as they were put in the bag ?—They were placed in two separate cubicles especially made for instruments.

Did you sterilise the instruments when Mr. Miles came back from an operation ?—Yes, always.

Did you count them ?—Yes.

In his presence or not ?—Yes, in his presence.

And when you had sterilised them, what did you do with them ?—I recounted them in Mr. Miles's presence and put them in the box again.

In 1919 and 1920, what Spencer-Wells forceps had Mr. Miles in his abdominal bag ?—He had six.

Miss Ruddock said that these were always the same six. There were no Spencer-Wells forceps in the rectal bag. She had never seen any other Spencer-Wells forceps in the flat in which they had lived at that time. Mr. Miles had had a case of instruments apart from the abdominal and rectal bag, but she could not say whether these other instruments had been kept at the flat or at the consulting-room, as she had been concerned only with the bags.

THE LORD CHIEF JUSTICE. Do you mean that, in addition to the contents of the bags, there was an instrument case where other instruments were ?—They were not at the flat.

But wherever they were, is that what you mean: that, apart from the contents of the two bags, there was somewhere an instrument case containing other instruments ?—Yes, but not at the flat.

Miss Ruddock stated in answer to Mr. Goddard that when Mr. Miles went out to an operation he used to say whether it was to be a rectal or an abdominal operation, and she used to lay the instruments out and he would count them with her, put them back into the tins, and shut the box. They would be the same instruments as had been used at the last operation and which she had sterilised and counted in his presence. She had never known him go out with either more or less than six Spencer-Wells forceps. He purchased a new set of stainless steel instruments at some time—about four years—after 1920. She had then placed all the old instruments in a box (produced) and put them away in a cupboard in the consulting-room at Park-crescent. She identified the six pairs of forceps which had been in the abdominal bag and said that she had never known him have any others in that bag. Since the cardboard box with the old steel instruments had been put away, she had never had occasion to go to it until 1928, when Mr. Miles had had a letter from the solicitors. The box had then contained the six Spencer-Wells forceps produced in Court, nine Lane, and six Kocher. This was the exact number that Mr. Miles had used in his abdominal bag. She had never had to do with any other forceps but these.

MR. GODDARD. How many needles and so forth did Mr. Miles have in his bag ?—He used to count the needles himself except a few needle-holders.

Yes, but how many other instruments were there in the tin ?—Three knives, three scissors, and six Moynihan clips.

THE LORD CHIEF JUSTICE. And those formed the contents of the abdominal bag ?—Yes, except, of course, the clamps; that is, one retractor and one clamp.

Cross-examined by MR. MORRIS.

The witness said that she had been with Mr. Miles since he had come back from the war. The instruments which he had brought back from the war had been in a case at Wimpole-street; she had not got them mixed up with any other instruments, as she was only looking after those in the abdominal and rectal bags. This case had been at Wimpole-street until it had been moved to the flat in 1924. It had been kept locked up. She did not work in fixed hours, and lived at the flat.

MR. MORRIS. If you were out and Mr. Miles came back from an operation, and if it is important to sterilise at once, he might do the sterilisation ?—I was never out when Mr. Miles went to an operation, in case there should be any messages for him. It is very seldom that I go out at all.

Mr. Miles might do his own sterilisation ?—He would not. I have never known him do it.

THE LORD CHIEF JUSTICE. What is the operation of sterilisation ? Does it take some time ?—It takes about three-quarters of an hour.

MR. MORRIS. And after the sterilisation you say that Mr. Miles always counts his instruments with you ?—Yes.

It must have happened sometimes that Mr. Miles was not there ?—Mr. Miles was always there. I never used to touch them unless Mr. Miles was there, and he never used to touch them unless I was there.

Who decided when instruments needed replating, you or Mr. Miles ?—If one needed replating, Mr. Miles would see it at the same time as I did.

And who would do the replating of it ?—The Holborn Surgical Instrument Co.

Who would send it there ?—I would take it there myself.

How often did it happen that Spencer-Wells were sent to be replated ?—It is hard to say, but they were not done more than six-monthly or yearly, and never unless Mr. Miles was on holiday and could afford to send them.

Do you remember anything about the marks on these instruments before they were replated ?—They had the same marks on as the original ones.

The witness stated that she had never had an inventory or written list of the Defendant's instruments but had been able to account for all of them in her head. There had been no Spencer-Wells in the rectal bag.

Re-examined by MR. GODDARD.

The witness said that she had that morning gone to Park-crescent and brought all the ordinary steel Spencer-Wells forceps that she could find. None of these had been at the flat or in the abdominal bag, but in the case at Wimpole-street, to which she had never had occasion to go. Inspecting these forceps, she said that three were marked Arnold, two Allen and Hanbury, and one H S I. These were the only other forceps in the possession of Mr. Miles.

In answer to Mr. Morris, Mr. Goddard said that this last envelope contained seven forceps in all.

Would not some form of inflammatory swelling be set up?—Yes, when the forceps perforated the bowel.

Would that inflammation tend to cause pressure against the rectum on one side and the bladder on the other?—Yes, if it were right down in the pelvis.

Might this cause the urinary trouble which the patient had complained of?—Yes.

Supposing that there was a foreign body actually in the small intestine, might there be some infection which would go upward and cause the metallic taste in the mouth which the patient described as like the taste of rusty nails?—That is very unlikely.

Could you tell me what would cause that persistent metallic taste?—There are certain medicines that cause it.

Might the presence of the forceps cause it?—I do not think so, I cannot see any connexion at all.

I understand that you can get an infection ascending from the bowels to the gall-bladder?—Yes.

That infection has an upward trend?—Yes, but that is an indirect infection of the gall-bladder. The organisms get in from the small bowel to the blood and then by the blood to the wall of the gall-bladder.

Sir Hugh said that he thought the stoutness of the patient did not affect the number of bleeding points in the early stage of the operation. If there were multiple tumours in the abdomen, there would be more bleeding points, which might sometimes be picked up by forceps of the kind in question. A surgeon often inspected the wound just before he closed it to see if any bleeding point had been left. Instruments were not often put on the patient but usually on the small tables fixed to the operating table, or standing by the surgeon.

Supposing you had ligatured a bleeding point and removed the pair of forceps and were going to use the forceps again in a moment, would you not put them down on one of the towels; for example, the towel which would be below the pubis in this operation?—You might.

Might there not be a number of instruments, a dozen or more lying about?—Yes.

Do you not agree that the counting of instruments is always only a means to an end, the end being to see that no instruments are left in the patient's body?—Yes.

I gather that there is nothing to prevent a surgeon from checking his instruments himself after the patient has been sewn up?—Nothing at all, after he has finished his operation.

And, unless the surgeon counts wrongly or is negligent in his counting, that test ought to be infallible?—It ought to be, but in practice it is impossible; it is not carried out.

THE LORD CHIEF JUSTICE. This Defendant says he did it. You say that the standard imposed in this case is a standard higher than the ordinary surgeon would be expected to observe?—Much higher.

Re-examined by MR. RAYNER GODDARD.

Sir Hugh Rigby said that he had heard Mr. Miles's evidence dealing with his own use of the aneurysm needle in the abdomen instead of forceps; that method was recognised as satisfactory, and there was then no necessity to use a Spencer-Wells. In reply to Mr. Morris, he said that the use of the aneurysm needle was not confined to larger blood-vessels, but was a matter of individual taste.

SIR THOMAS JEEVES HORDER.

Examined by MR. RAYNER GODDARD.

Sir Thomas said that he had known Mr. Miles as an operating surgeon for about 25 years, and that Mr. Miles had operated on a considerable number of his patients. The Defendant's methods were those of a careful surgeon. The witness himself attended at serious operations. He knew Mr. Miles to be very careful in his methods of checking his instruments; if he had not thought so he should not have nominated him to operate on his patients. Sir Thomas enumerated the persons who usually took part in a surgical operation. The duty of checking instruments, swabs, and sponges was laid upon the theatre sister.

Is the surgeon himself in your opinion able to do that?—I regard him as responsible for the sister's competence to do it, but I should not regard it as in the patient's interest that he himself should feel it necessary constantly to watch the instruments in the last stages of an operation.

THE LORD CHIEF JUSTICE. It is said that at the conclusion of an operation, after the patient has been sewn up, there may be a duty upon the surgeon to see that the count is correct, so that if it does not appear to be correct, the mischief can at once be attended to. What do you say to that?—I agree, my Lord; that is the surgeon's responsibility. I regard the surgeon as being ultimately responsible for all these matters.

MR. GODDARD. Is there any possible precaution that you can suggest beyond counting the instruments before and after the operation?—Assuming that the counting is done by a competent person, I cannot suggest any further precautions. That seems to have reduced things to the simplest and safest of terms.

THE LORD CHIEF JUSTICE. What would be your observations upon a surgeon who said, "Nobody counts the swabs and nobody counts the forceps?"—My Lord, I should not nominate that surgeon to operate upon my patients.

Sir Thomas said that after an abdominal operation there was always some pain, but not necessarily considerable pain. There was always some abdominal pain after a hysterectomy; in a normal case this pain continued for a few days, perhaps two weeks, depending upon the idiosyncracy of the particular patient. He had seen quite a number of cases of ventral hernia after abdominal operations. This was due to several factors, including the extent of the operation, the extent of the incision, and the personal idiosyncracy. Obesity and lack of muscular tone were great determining factors. This ventral hernia was not usually accompanied by pain, but pain might be present. He should not expect the presence of a pair of forceps in the abdomen to manifest itself by an external lump unless considerable inflammation and suppuration had occurred, and an abscess had formed. A lump could only be formed by an abscess.

MR. GODDARD. The Plaintiff has stated that from a very early stage, two or three months after the operation, a lump the size of a cocoanut appeared on her abdomen in the neighbourhood of the scar. Could that be caused by the presence of the forceps?—No.

The surgeon who operated in France for the gall-bladder trouble stated that the gall-bladder was very diseased and thickened and adherent to the surrounding parts. Would that condition be consistent with a sudden onset of gall-bladder trouble, or would it indicate a chronic state?—A chronic state with possibly acute complications, but it sounds as though it had been in existence for some years.

Patients might complain, Sir Thomas said, of gall-bladder pain in any part of the abdomen, if for no other reason than the associated flatulent dyspepsia. He described the cause of dysentery and said that gall-bladder infection was not a usual consequence. The presence of a pair of forceps in a fold of the intestines could not cause either gall-bladder trouble or dysentery. Judging by the symptoms as described to him by Mr. Goddard, he assumed that the forceps had not penetrated the small intestine.

Cross-examined by MR. MORRIS.

Sir Thomas Horder stated that it was impossible to say whether the adventitious matter on the forceps was fæcal matter or not. From its appearance it might be, but its nature would only be certain if a chemical analysis were made. He had had no experience of a case in which a pair of forceps had been left in the body.

A foreign body lying within the coils of the intestine might penetrate it. In answer to the Lord Chief Justice, he said that perforation was necessarily accompanied by irritation and ulceration. A foreign body would inevitably cause the formation round it of fibrous tissue, and adhesions were the result of inflammation. Blood in the fæces might be caused by the presence of a foreign body. An abscess might form around a foreign body even if it were sterile.

Mr. MORRIS: After the gall-bladder has been almost entirely removed, ought not the symptoms to disappear?—It is most desirable that they should, but they do not always do so. There is no "ought" about it.

If there were a persistence of some pain identical with pain that had been existing for a long time, would not the irresistible inference be that that pain was not one of the gall-bladder pains?—Not irresistible.

Would it be a most probable inference?—If, as I understand it was, the gall-bladder in this case was very grossly diseased. I should think it would be optimistic to expect a hundred per cent. freedom from discomfort after its removal.

Would it be a most probable thing for the persisting pain to discontinue?—I should hope persistent pain would disappear if the diagnosis had been correct.

If a pain which had been persistent disappeared after forceps were removed, would the interference be irresistible that the pain was caused by the forceps?—Your word "irresistible" is one with which we are not familiar in medicine, but if you will talk in terms of probabilities, then I should say that if the patient had complained consistently of a pain, and that a pair of forceps such as I have seen had been removed from the abdominal cavity, then even I should be optimistic enough to hope that the pain would disappear.

The witness was not re-examined.

MISS SARAH JANE KINGMAN.

Examined by Mr. RAYNER GODDARD.

Miss Kingman said that she was a State-registered nurse. Between 1920 and 1924 she had attended many operations at the Hydro. She remembered the operation upon Mrs. Crotch quite well; it was the first operation performed by Mr. Miles at which she had been present. She had worked with Nurse Brown, who was a very competent theatre sister. She had helped to wash the instruments after the operation, but it had been the duty of the theatre sister to count them. There had been ample time to count them, as the theatre sister had very little to do at such an operation. The instruments had been counted after this operation; this was a sacred duty. The sister knew how many there should be, because she had sterilised them before the operation and had then counted them with the surgeon. That also was a sacred duty.

Cross-examined by Mr. MORRIS.

Miss Kingman said that she had been employed at the home and had not come in specially for the operation. The average number of operations at the Hydro was not one a day.

DR. HENRY EDMUND GASKIN BOYLE.

Examined by Mr. DICKENS.

This witness stated that he had given anæsthetics for Mr. Miles for about twenty-five years at many operations. He testified that Mr. Miles was a very skilful and careful surgeon indeed. Mr. Miles always used large forceps inside the peritoneum and small ones at the beginning of the operation for picking up the vessels before the peritoneum was cut. The large forceps were called Kocher forceps. By the time the peritoneum had actually been severed the small forceps had been removed from the table. This was the invariable practice at Mr. Miles's operations. He had been struck many years ago by Mr. Miles's practice of putting out his instruments in multiples of three, a practice from which he had never known him to depart. He would hand them to the theatre sister in threes or multiples of three and she would put them into the steriliser. At the end of the operation he would ask the theatre sister if the count was correct; he had never known Mr. Miles fail to do this. Mr. Miles brought his instruments to the theatre in a regular bag, and would lay out only those which he required.

Cross-examined by Mr. MORRIS.

The witness stated that even if a patient's heart was reported to be failing, he did not allow panic. He admitted that the anæsthetist could not always follow every step of an operation.

This witness was not re-examined.

DR. JOHN SOUTHERDEN BURN.

Examined by Mr. DICKENS.

Dr. Burn stated that he had given the anæsthetic at the operation on Mrs. Crotch. Before and since this time he had given many anæsthetics for Mr. Miles. He corroborated the testimony of other witnesses concerning Mr. Miles's practice in counting his instruments with the theatre sister. The theatre sister, he said, would be able to say at any stage of the operation how many instruments were in the body. Mr. Miles would never sew up the wound without getting information from the sister that all the instruments had been accounted for, and according to the witness's recollection he had never departed from this practice. Mrs. Crotch had not borne the operation very well, but had collapsed somewhat towards the end. The witness remembered this particularly, having a particular reason to do so. He had seen English-made forceps, including Spencer-Wells, sold in Étaples at the end of the war; they were surplus Army stores and were going very cheap.

Cross-examined by Mr. MORRIS.

Dr. Burn said that the only structure removed at the operation had been a fibroid uterus; no other tumours had been removed.

If the patient was not taking the operation very well, what would be the effect upon the remaining course of the operation?—The operation would be completed as soon as and as safely as possible.

Would the termination of the operation be in any way expedited?—Yes; Mr. Miles might be able to put on a little extra speed which he would not use if there were no hurry.

This witness was not re-examined.

THE LORD CHIEF JUSTICE'S SUMMING-UP.

Counsel on either side having addressed the jury, THE LORD CHIEF JUSTICE said that this was a case of no little importance and difficulty. The case for the Plaintiff could not have been more elaborately and emphatically presented than it had been by learned counsel, but he warned the jury against being misled by the appeal to the emotions which had been quite legitimately made by her advocate. The task the jury had to perform was a scientific, not an emotional one. He continued:—

"Let me refer to one expression used yesterday by the Counsel for the Plaintiff. I do not know what impression was conveyed to your minds, but it seemed to me to be intended that should this action result in a decision adverse to this eminent surgeon it would involve no reflection on his general skill and standing. Can you accept that suggestion? It is quite idle to say that the reputation or the skill of the Defendant is not involved in this case. But the question is not whether it is desirable or permissible that a patient who undergoes an operation should afterwards be going about with a forceps in her body—nobody suggests that, and everyone must have the greatest sympathy with this lady—but the question here is, who did it? When something which excites strong feelings of passion or indignation has happened, if the mind is allowed to be filled with those feelings, do they help it in a strictly *scientific inquiry*?

"The learned Counsel for the Plaintiff began the last passage of his speech by a rhetorical enumeration of the points he conceived to be strongly against the Defendant. He said in effect, 'You are told that these instruments and swabs are not counted when an operation is done in France? What does that matter if you are satisfied that these were the forceps of the Defendant?' I choose that question as indicating to you the kind of fallacy into which it would be most unfortunate to slip. You are inquiring whether these are the forceps of the Defendant. How can you be satisfied that these are the Defendant's forceps when you now know by the mouth of the Plaintiff's own witnesses that forceps and swabs are not counted in France? Of course, if you are satisfied that these are the forceps of the Defendant, what was done in France does not matter. But it is vital to have regard to what was done in France in order to know whether you may properly inquire whether these are the Defendant's forceps. Let us put the matter the other way round. Suppose that the evidence about the operation conducted by Dr. Prat in France was that for years he had been conducting operations with the assistance of a careful method deliberately designed by himself to prevent an error about the number of instruments [illegible] swabs; suppose that Dr. Prat had been able to say, [illegible] *have designed a system of multiples of three.* [illegible] count myself, the theatre sister counts, I check the counting of the theatre sister.' Suppose that had been the evidence about Dr. Prat's operation, and suppose when it came to Mr. Miles's operation he had had to say, 'I never count at all, and nobody counts for me, it is not done,' how indescribably stronger the case against the Defendant would have been. Now, you see, the position is reversed. The evidence of care in counting and of method in counting is the evidence of the Defendant and the evidence given on his behalf, and it is conceded that in French operations there is no counting by the surgeon or by another. You may think it right to say that the measure of the additional strength that would have been given to the case against Mr. Miles if the position had been reversed is the measure of the *assistance which his case derives from the knowledge* which you now have that in the French operation there is no counting."

His Lordship then laid down the questions which the jury had to decide:—

(1) Is it established that the forceps were left in the Plaintiff's body in the course of the operation performed by the Defendant?

(2) If so, was that fact due to negligence on the part of the Defendant or for which he is responsible?

(3) The question of damages, if it arises.

He then discussed the question of damages. In addition to the medical fees and expenses incurred, he pointed out that the Plaintiff claimed £500 lost by her through having to leave Paris because of her ill-health. He asked the jury whether it was right to attribute that loss to the presence of these forceps. There was also a claim for £100 loss on profits in the Plaintiff's business, an antique shop at Vence, near Nice, which she had had to give up. This, however, related to the period antecedent to the following on the operation carried out by Dr. Prat for gall-stones. Two things were involved in this claim—namely, that the trouble in the gall-bladder was caused by the presence of the forceps, and that in consequence of the necessity of that operation this loss of £100 was incurred. The question with regard to these and other figures was whether the jury thought it clear that these losses had been incurred and were attributable to what had been done or omitted at the operation in 1920.

The Liability of the Surgeon.

Lord HEWART continued:—Nobody denies for a moment that if a surgical forceps is left in the body of the Plaintiff in the course of a surgical operation, that patient ought to have a remedy in damages against somebody. The whole question here is, *however: Is the liability of this Defendant made out?* If you are satisfied that it is, you will not hesitate by your verdict to give expression to that view. There are few things so extraordinarily difficult to trace with certainty and assurance as the relation of cause and effect. What you are invited to do here is to say that it is established beyond reasonable doubt that this surgical instrument was left in the Plaintiff's body in November, 1920, under circumstances which involved the operating surgeon in personal liability. What is the personal liability of the surgeon? It is not quite a simple question. As the case went on and the evidence accumulated, the question underwent a certain development, and it is necessary to distinguish between different things. Let me remind you of a passage in the evidence that was given on commission on behalf of the Plaintiff by Dr. Fay, the surgeon who carried out the final operation for the removal of the forceps in September, 1928. He stated that for operations of this kind the surgeon must be assisted by a team—an assistant, an anæsthetist, and one or two sisters, and each member of that team has his or her particular part in the operation. Dr. Fay was asked, "If the surgeon knows and trusts the members of the team, he will not interfere with their particular part in the operation?" The answer was "Yes." "He will *not* interfere with the giving of the anæsthetic?" "Quite so." Dr. Fay was further asked, "Is it not the practice of the surgeon to leave the counting of the instruments and swabs to a sister?" Dr. Fay answered, "It ought to be like that." A further question was, "Then it is possible for the surgeon or his assistant to leave instruments or swabs in the body without personal negligence?" and the answer was "Yes, it is possible."

Let me remind you of what was said by Mr. Miles as to the usual practice. He described to you in detail his method based on an enumeration of threes, and how when he arrived at the scene of the operation he handed over the instruments to the theatre sister. "I count them out to her and show her that they are in threes and multiples. She sterilises them and lays them out on the special table. This is done while I am making myself aseptic. In an abdominal operation like this the incision is made below the navel; it goes through the skin and the subcutaneous tissue and fatty tissue, and always there are three or four bleeding points. I use Spencer-Wells 5-inch pressure forceps to seize these vessels to enable me to tie them. I generally do the tying and my assistant removes the forceps. Sometimes it is the other way round."

Lord HEWART then read other portions of Mr. Miles's evidence, showing the method whereby the carefully trained theatre sister carried out the counting of the instruments and swabs. He continued: All the evidence on this question of the relative responsibilities and liabilities of the theatre sister and the surgeon has come from the Defendant's side. The Plaintiff's evidence is extremely interesting for what it says. You may think when you apply a critical eye to it that it is in some places not less significant for what it does not say. The evidence of the doctors in France taken on commission, and on this particular point the evidence of Dr. Fay, is that you look to the theatre sister. Not so with the evidence adduced on behalf of the Defendant. Sir Hugh Rigby stated that in attendance at the operation are the surgeons, the assistant, the theatre sister, generally two nurses, and the anæsthetist, that the theatre sister is responsible for the instruments, the sterilisation of the instruments, the towels, and the swabs, and that she is very highly trained for this work. Sir Hugh Rigby said, "In our country she is something quite apart. She is especially trained for this duty, and has responsibilities which sisters in other countries are not given because they are not trained. I do not think one person can be responsible for all the details of the operation. The duty of counting instruments or swabs falls, according to the usual practice in this country, upon the theatre sister." Then came this passage, of no little importance in this case. "My own practice is to do nothing"—this is Sir Hugh Rigby speaking, the King's surgeon—"and if the sister finds that she has not the right number she tells me. If I hear nothing I take it that all is correct. It is very seldom that I myself inquire. If I were working in a strange place, or did not feel confidence in the sister, I might do so." Sir Hugh Rigby also said that it was in the interests of the patient that the duty of counting should be left to the sister. He said that unless he was warned by the sister he was not expected to make a search. It would be against the interests of the patient for the surgeon to have extra manipulations to perform. He went on to say that the standard of care in this matter of enumeration which was set and observed by the Defendant was a standard higher than the ordinary and a standard to which the ordinary surgeon could not be expected to attain.

Then came Sir Thomas Horder. Sir Thomas Horder is a physician, and he expressed the physician's point of view. He regarded the ultimate responsibility as depending upon the surgeon. He said, "I agree that the surgeon's responsibility is at the close to check the counting. I regard the surgeon as ultimately responsible in all these matters." What emerges from that evidence, and from other evidence like unto it? You may think it is right to draw a distinction between what is done in the course of the operation and what is done immediately at its close. It may well be that in the actual course of the operation, while the surgeon is cutting and opening and attending to his surgical task, it is not to be expected nor desired that he should be busying his mind with the counting of instruments or swabs or with the question of whether a swab or instrument is missing. But you may think that other considerations apply at the close of the surgery itself. It may well be that any delay might be highly prejudicial if it occurred before the body of the patient was stitched up, but after that you may think that before the surgeon departs it is reasonable that he should personally satisfy himself that the number is correct, and that there is nothing missing. Mr. Miles says that he does that. Sir Hugh Rigby said that it is not usual, and he himself does not do it. These questions are very material as regards the second question I have put to you, but that question, of course, does not arise at all unless you are satisfied that the forceps were left in the body of the patient at the operation of 1920. If you are satisfied as to that, the question then arises as to whether this was due to negligence on the part of the Defendant or negligence for which he was responsible. This is not quite a simple question. What is it that the surgeon undertakes? I quote the words of Lord Chief Justice Tyndall a hundred years ago, but unimpaired in their effect:—

> "A person entering a learned profession undertakes to bring to the exercise of it a reasonable degree of care and skill. He undertakes to bring a fair, reasonable, and competent degree of skill, and you will say therefore in this case that the injury was occasioned by the want of such skill in the defendant."

Skill must be also accompanied by diligence, and you have to decide (if this question arises) what exactly are the position and the responsibilities of the surgeon in the matter. Of course, you and I are looking back upon this matter after the event has happened. There are few things so unhelpful as the wisdom that follows the event. You have to put yourselves for this purpose at November, 1920. Was it in November, 1920, part of the duty of the surgeon personally to count the instruments and satisfy himself that the number was correct, or was he entitled to say that there was present a skilled theatre sister, that this was her job, and that he was entitled to act upon her report? She is not his servant, she is one of the team. We can all make mistakes. I suppose it is quite conceivable that somebody in an individual case might miscount a certain instrument. You have to address your minds to this question: suppose the theatre sister did miscount and thought there were six of these instruments when there were only five, is the Defendant responsible for that happening? Is it a breach of duty on his part that the theatre sister made that mistake? You may think it is linked up with the question as to what he did afterwards. If the evidence given on behalf of the Defendant in this case is accepted, it is exceedingly difficult to entertain the view that this forceps got into the Plaintiff's body in November, 1920.

Apropos of that observation, let me remind you of this, that when in these Courts a Plaintiff is seeking to recover damages for something wrongful which is said to have been done actively or by omission, then the burden of proof is on the Plaintiff to show that that complaint is made out, and is made out against the very Defendant. The proof is not the other way round. It is not for the Defendant to prove a negative. Indeed, as this case has gone on, you may have reflected how wise our ancestors were in devising Statutes of Limitations, preventing some kinds of action being brought after four years, and most kinds of action from being brought after six years. Why? Because it is so uncommonly difficult to recollect with accuracy what precisely was done so many years ago. It would be intolerable if, when an allegation was made about something done nine or ten years ago, the burden of proof were upon the Defendant. In the extremely difficult question of tracing cause and effect we must never lose sight of the fact that the burden of proof is upon the Plaintiff. If you are satisfied that that burden has been discharged, the conclusion is clear, but if you are not satisfied, if you are left in real doubt, equally the conclusion is clear, that the case is not established."

Lord HEWART then remarked that this type of accident, revolting to the mind as it was, was a sort of accident that happened very rarely. In more than thirty years' experience of courts of law he himself had never known anything like it. It was something very rare, but if there was no counting by the surgeon or by anybody on behalf of the surgeon, was it difficult to understand that such a thing might conceivably happen? Might not the absence of counting explain how it came to happen? The thing which was being dealt with here was a thing called a forceps, superficially like a pair of scissors, but having a very different function. The function of the forceps was to hold firmly. When the bleeding points were exhibited in the course of the operation the forceps were used to take up each point, pinch it, and stay the bleeding. The forceps having played its part, there followed the use of the ligature, and when the ligature was put on the forceps might be removed. The effect of this was that the forceps might be there for an appreciable time; there might be a row of forceps, and when the forceps were removed, if there was no counting, and especially if the patient was rather stout, the loss of a pair of forceps was a thing which might possibly happen. The fundamental contrast between the practice in counting on this side of the Channel and on the other was the first thing that leapt to the eye. The next thing was the remarkable contrast in the Plaintiff's evidence as between the amount of medical evidence relating to 1926 and the paucity of such evidence during the period from 1920 to 1926. Mr. Miles, in his evidence, had said that when the patient came to him in May, 1921, to the best of his recollection there had been no hernia, because if there had been he would have reported it to the patient's doctor, Dr. Wadd, and would have suggested a belt. Dr. Wadd had testified that he had seen the patient in January and February, 1921, that she had had insomnia and nervous exhaustion, as well as domestic worry, but that she had never led him to think that she had anything wrong with the abdomen. There had been no swelling, no hernia, no bulging; she had never directed his attention to any lump. The Plaintiff had afterwards gone to Margate and stayed there till the end of September. She gave a poor account of her condition, but no doctor who had seen her at Margate had been called to give evidence. In India and in Paris there was again no medical evidence. If that forceps had been in the lower part of her abdomen during those five and a half years, how came it that there was this gap in the medical testimony? There was, of course, the evidence of Dr. Stevens, whom the Plaintiff consulted in 1921, 1922, and 1923. Altogether, spread over those years, there were 21 occasions on which Dr. Stevens had his attention directed to the Plaintiff. He had said that the Plaintiff was complaining of pain low down in the abdomen, swelling in the middle line of the abdomen, attacks of nausea and vomiting. He knew of her operation, and said that she had had a ventral hernia. Ventral hernia was a very common sequel to an abdominal operation in a fat subject. Dr. Stevens had never suggested that it was a case for an X ray examination to see if there was some foreign body left in the abdomen. Was it to be supposed that if, by manipulation or otherwise, Dr. Stevens had detected the presence of a foreign body, he would not have called for an X ray examination? His conclusion had been that that which he saw was consistent with the ordinary consequence of an abdominal operation. How came it also that nobody who had examined the Plaintiff in Bombay had suggested an X ray photograph? The Plaintiff had said that the lump had always been there, about the size of a small cocoanut. The doctors in the hospital at Bombay had examined her and, presumably, noticed a lump. Was it to be supposed that these medical men, if they had suspected the presence of a foreign body, would not at once have taken steps to see whether there was not some foreign body there? The Plaintiff had said that the pain had continued daily for eight years until the removal of the forceps. The question was whether that was not an exaggerated statement. She had also said she had felt as if she had been eating rusty nails. That expression threw a good deal of light on this story. Who knew what it felt like to have eaten rusty nails? Was it not the very sort of picture which might occur to a somewhat imaginative person looking back after a period of time when she knew that a pair of forceps had actually been discovered in her abdomen?

Lord HEWART then asked whether it was credible that if during all this time she had been suffering in the way she had described, and had had a lump of this kind, she would not have seen the surgeon who had performed the operation. She had explained the fact that she was silent about it by saying that he had assured her on her visit in May, 1921, that there was nothing vital the matter and that she must regard this sort of thing as a necessary consequence of the operation. Finally, had come the operation of June, 1926, by Dr. Prat, and the Defendant had suggested that this forceps had been left in the Plaintiff's body by some inadvertence on that occasion. The proof that this was so did not fall upon the Defendant, but what he said was that, when all the surrounding circumstances were considered together with the actual course of the operation of 1926, it could not be said that these forceps had entered the patient's body during the operation which he had performed in 1920.

JUDGMENT.

The jury, after a short absence, found that it had not been established that the forceps had been left in the Plaintiff's body in the course of the operation performed by the Defendant.

The LORD CHIEF JUSTICE thereupon entered judgment for the Defendant, with costs.

Special Articles.

MEDICAL INVENTIONS AND PATENTS.

VIEWS OF THE BRITISH SCIENCE GUILD AND THE JOINT CHEMICAL COMMITTEE.

A REPORT on reform of the British patent system, recently issued by the British Science Guild (6, John-street, Adelphi, London, W.C. 2. 2*s.*), dealt incidentally with the patenting of biological inventions. The Committee was appointed by the Guild in April, 1927, to consider what changes could advantageously be made in British patent law, and only reported after holding 18 full meetings and preparing and circulating many memoranda. Its chairman was Mr. W. H. Eccles, F.R.S., President of the Physical Society, and its hon. secretary Capt. C. W. Hume, B.Sc., joint hon. secretary of the Guild. In an introductory note the fundamental object of the patent system is described as an encouragement to the establishment of new industries and the improvement of old ones by the granting of temporary monopolies, owing to the protection afforded by which manufacturers and financiers are induced to risk their energy and capital. In the absence of a patent system the practice of secret working grows apace, and this may well cost the manufacturer more than the open working of a patent system, and have the further objection of postponing or even preventing publication. Holland, which abolished its patent system in 1869, reinstated it in 1912 owing to the decline in its manufactured exports. The patent system, it is held, is useful to the community in a variety of indirect ways; inventors are encouraged to embody their ideas in specifications which promote the free circulation of new ideas, while the collected specifications record the growth of applied science hardly possible in any other way.

Research and Invention.

Modern research has, however, altered the volume of invention, notably in the chemical and biological sciences, and has made it harder than it was before to define an invention, for invention may be a flash of intuition or it may be the result of a system of research by a scientific staff. It is difficult to draw a clear distinction between such a process of research and the use by a skilled workman of the known rules of his art—and in law no patent is valid unless the invention contains "subject matter." In practice the Guild sees no reason why patents should not be granted to protect improved biological products, and considers it desirable to extend the interpretation of the word "manufacture" so as to permit of the patenting of a wider range of biological inventions. In view of the strong contrary opinion of the medical profession the Guild considers that biological inventions subserving medical treatment should not be patentable.

Taking this report as the basis of consideration, the Joint Committee, including eight of the principal chemical associations of the country, has formulated its own proposals, which have now been issued in a memorandum (from the Joint Chemical Committee, 116, Piccadilly, London, W.1. 1*s.*). Mr. A. Rée, Ph.D., and Mr. F. H. Carr, D.Sc., have acted as chairmen of this Committee, which had Mr. J. Davidson Pratt, F.I.C., for its secretary. The Joint Chemical Committee acknowledges the services rendered by the Guild in indicating clearly the need for changes in our present system and in submitting constructive proposals to this end. Medical inventions are dealt with in a short section of the memorandum, and in great detail in an appendix thereto.

The subject of patents for inventions subserving medical treatment has received long and detailed consideration from the Joint Chemical Committee. While it is at present permissible, the memorandum states, for patents to be obtained for medical inventions, the position is very unsatisfactory, and British industry and research are being handicapped in that the results of British investigations are being exploited by foreigners who have not the same feelings in regard to medical patents as the British medical worker. Some solution of the difficulty should be found which will meet the objections of the medical research worker to patents on ethical grounds and the desire for sufficient protection on the part of the manufacturer, whose coöperation is essential if the public is to obtain full value from new medical discoveries. There is a choice between:

1. No medical patents at all, being the view advocated by the British Science Guild in regard to biological inventions in the medical field;
2. A system of medical patents devised to meet the two points of view already indicated.

While a non-patent system may find favour in medical circles, it does not afford the necessary protection to manufacturers, and may in practice lead to the extended use of secret manufacture and secret remedies, with results which are objectionable both on general grounds and in regard to the restrictive effect on further research. In any case, the abandonment of medical patents by this country, without international agreement on the subject, would place both our research workers and our manufacturers at a serious disadvantage.

The Present Position.

Section 38A (1) of the Patents and Designs Acts 1907 and 1919 (Consolidated), is as follows:—

> "In the case of inventions relating to substances prepared or produced by chemical processes or intended for food or medicine, the specification shall not include claims for the substance itself, except when prepared or produced by the special methods or processes of manufacture described and claimed or by their obvious chemical equivalents; provided that, in an action for infringement of a patent where the invention relates to the production of a new substance, any substance of the same chemical composition and constitution shall, in the absence of proof to the contrary, be deemed to have been produced by the patented process."

Under this Section, therefore, it is possible to take out patents for medical remedies, which may be divided roughly into two main classes:

(*a*) Definite chemical compounds, with a specific effect in certain diseases. Such inventions usually arise from purely chemical investigations, and the medical research worker only intervenes at the stage of pharmacological and clinical trials;

(*b*) Biological productions such as vitamins, insulin, serums, vaccines, &c. These products generally originate with the medical research worker, but the chemist (or biochemist) comes in, during the later stages when isolation and investigation of the active principles (e.g., adrenalin, thyroxine) of such products is attempted.

These two classes may overlap, but it is clear that there are two groups of workers concerned—chemists and medical research workers.

Medical Objection to Patents.

Chemists as a body appear to have no objection to taking out patents for substances used for medical treatment, since eminent chemists, including university professors, are to be found among British patentees of such products. It is, however, quite otherwise with the medical profession, a large section of which is believed to be resolutely opposed at present to taking out such patents, whether they be of purely chemical or biological origin, and the following are the two main arguments advanced.

In the first place, the medical profession is peculiar in its special relation to human life and suffering, and when doctors prescribe a particular drug they are expected to be free from any suspicion of financial bias in its choice. A patent in relation to any medical remedy tends at first sight to give the impression of making profit out of human suffering.

The second and more important objection, the validity of which is, however, doubtful, is that the freer use of patents would result in greater secrecy on the part of research workers, whereas the fullest and freest interchange of knowledge and mutual assistance between workers in different laboratories is essential for progress.

Secrecy would undoubtedly have a very adverse effect on medical research because of the complexity of the problems, and the necessity for the full and rapid publication of all information bearing on them. There is, however, some doubt as to how full and early publication can best be assured.

Knowledge and Reward.

The object of our patent law is to stimulate invention by offering a reward, and to extend industry in this country by the application of new discoveries. In other fields it succeeds in that object, even though in them, as in medicine, it often happens that the patented invention does not benefit the actual discoverer of the knowledge on which the invention depends. While this is a state of affairs very difficult to avoid or to remedy, it is important to seek for compensating influences thereto. The border line between discovery and invention is very difficult to define in medical fields. A medical discovery is often the culmination of years of progressive research by many workers, and it is manifestly unfair that the worker who is lucky enough to take up the work at a certain stage when most of the work has been done, and who merely puts the finishing touches to it, should be able to reap the sole monetary reward of the cumulative effort. Such a state of affairs usually discourages scientific workers who have contributed largely to the research on which the invention is based, when they find that the knowledge they have freely provided is being monopolised by the inventor of perhaps merely a small addition or modification. The fact remains, however, that the general motive of most scientific workers is the satisfaction of advancing knowledge and not monetary reward.

Three Instances.

The memorandum proceeds to glance at the circumstances surrounding one or two important instances in which the question of patents has been involved in connexion with inventions subserving medical treatment.

1. *Insulin.*—In 1923 Dr. Banting made the final addition to a long series of discoveries by which the preparation of insulin was rendered possible. This was protected by a patent taken out in the name of the University of Toronto, where Dr. Banting was working. The British patent rights were offered by the University to the Medical Research Council, whose action in accepting them caused much unfavourable comment in the medical profession and some opposition by important men of science. It is understood that the Council did so on the grounds:

(*a*) That the patent was better in their hands than in anybody else's;

(*b*) that it enabled them to exercise the power which was necessary in order to secure the proper use of the knowledge and to control the manufacture of insulin, there being at that time no Therapeutic Substances Act by which this could be effected.

It is agreed that events have fully justified this action, as it has resulted in insulin of the highest quality being now available at very low cost, owing to the fact that the few firms to whom the manufacture was entrusted were enabled thereby to devote considerable energy and capital to developing efficiency in manufacture and a high quality of product.

2. *Thyroxine.*—At the time that Dr. Harington published all but the final stage of the synthesis of thyroxine, he decided not to patent this method, and thus he left unguarded the possibility of other workers, perhaps abroad, obtaining a monopoly of synthetic thyroxine by discovering the last step. As it happened, Dr. Harington was later successful in completing the synthesis, which was never patented. Though there is now no master patent, there remains the danger, however, that some foreign manufacturer may become possessed of some patent which, though

It will be noted that the general tendency of the recommendations of the committee is toward (1) a more complete centralisation (as regards professional appointments), and (2) a better coördinated service. If they are made effective the further step of transforming the public medical service into a State Medical Service will be short and easy.

Actions for Damages for Alleged Illegal Detention.

An application was heard by Mr. Justice O'Byrne, in the High Court, Dublin, recently, to stay, on the ground that it was frivolous and vexatious, an action brought by Mr. Patrick Moore against Dr. J. O'C. Donelan, resident medical superintendent of the Grangegorman Mental Hospital, for damages for alleged illegal detention. Having heard counsel for Dr. Donelan, and the plaintiff who appeared in person, the judge made the order asked for.

He said that it appeared that the plaintiff was detained in Grangegorman Mental Hospital from May 6th to June 28th, 1927, and his action was concerned with that detention. It also appeared that he was apprehended by the Civic Guards and brought before Mr. Kenny, who was acting as District Justice in the Dublin Metropolitan Court. Mr. Kenny, acting in that capacity, made an order that the plaintiff be forthwith detained in the district lunatic asylum That committal warrant was admittedly made by Mr. Kenny in that capacity, and it had never been set aside. Mr. Moore was taken to the institution in pursuance of that warrant and detained. His lordship also referred to the order of the Chief Justice removing the plaintiff to e care of Dr. Eustace, and said that in the circumstances seemed to him that there was no illegal imprisonment y Dr. Donelan. Not only was the detention of Mr. Moore not illegal, so far as Dr. Donelan was concerned, but Dr. Donelan was absolutely bound in pursuance of the warrant to take Mr. Moore into the institution and detain him until he was legally removed. It seemed to him that the action was frivolous and vexatious, and an abuse of the process of the Court, and could never succeed.

An action for damages on similar grounds taken by the same plaintiff against Dr. W. N. Eustace, of Hampstead Private Asylum, Dublin, was subsequently stayed on an application to Mr. Justice Sullivan. The plaintiff had been removed from Grangegorman Mental Hospital and put under Dr. Eustace's care by order of the Chief Justice, and had been detained there from June 28th, 1927, to Jan. 25th, 1929, when by a further order of the Chief Justice he was removed to Carlow Mental Hospital.

The same plaintiff also took an action for damages against Dr. M. S. Walsh, dispensary medical officer, for alleged negligence in the issuing of a false medical certificate on May 16th, 1927, thereby causing the plaintiff to be imprisoned in Grangegorman Mental Hospital. Dr. Walsh had been ordered by the District Justice to examine and give evidence as to the mental condition of the plaintiff. An application for a stay in this case was adjourned by Mr. Justice Sullivan for the filing of a further affidavit.

The Sweepstakes Bill.

The Public Charities Hospitals (Temporary Provisions) Bill, commonly known as "The Sweepstakes Bill," which was introduced to the Dail by Sir James Craig, and passed its second reading a week or two ago, has now been returned to the House after consideration by a Special Committee. It has been amended in several respects. One amendment provides that only hospitals which reserve at least 25 per cent. of their beds for non-paying patients, and which exercise no discrimination in the filling of the beds on the ground of the religion of the applicants, are to be permitted to enjoy the privileges granted by the measure. A non-paying patient is one defined as paying less than 10*s.* a week. By another amendment institutions are excluded from the benefits of the Bill if there be in their charter, constitution, or regulations any provision debarring any person from appointment to the staff solely because of his or her religious belief. Another amendment provides that the amount to be deducted as expenses for the conducting of a sweepstake shall not exceed 30 per cent. of the money resulting from the sale of tickets. It is doubtful whether the measure will become law or not. Public opposition to it has been increasing, and most of the religious bodies have denounced it as encouraging gambling. Certain hospitals, too, which a little time ago were willing enough to benefit by sweepstakes, are now publicly expressing their disapproval.

The Irish Radium Institute.

The President of the Royal Dublin Society (Prof. John Joly, F.R.S.), announced last week that it was proposed to appeal for further support for the Irish Radium Institute. This institute, which is conducted in association with the society, has often found itself unable to meet the demand for radium emanation required for therapeutic purposes. The society hopes to raise a sum of £12,000, of which £2000 has already been guaranteed. Dr. Joly rightly takes pride in the fact that the method of using radium emanation in needles implanted in the tissues, now commonly employed, was first introduced in Dublin.

The Queen's Institute of District Nursing.

The annual general meeting of the Queen's Institute of District Nursing in Ireland, usually known as the Jubilee Nurses, was held last week, and a satisfactory report was presented. A year or two ago a movement was on foot to disrupt the institute between the Irish Free State and Northern Ireland, but the attempt failed, and while each division of the country now enjoys a certain degree of local autonomy, the central control for the whole of Ireland rests with a Joint Council.

Vacancy on the Irish Medical Registration Council.

The regretted death of Mr. Maurice Hayes has caused a vacancy on the direct representation of the medical profession on the Medical Registration Council of the Irish Free State. Up to the present the only candidate who has announced his intention of coming forward is Mr. William Doolin, F.R.C.S.I. Mr. Doolin is a graduate of the National University of Ireland, and one of the Surgeons to St. Vincent's Hospital. He has been honorary secretary of the Dublin Local Medical Committee for several years, and is the editor of the *Irish Journal of Medical Science.*

ROYAL WATERLOO HOSPITAL.—The report for last year records an improvement in the finances, due principally to legacies, which were especially welcome since the accumulated deficit was becoming a serious embarrassment. There were 2098 in-patients who cost £8 1*s.* 1*d.* each for an average stay of 18 days, and 16,000 new out-patients; each out-patient cost 7*s.* 7*d.* A further extension of the out-patient department is necessary, but the difficulty of obtaining a site has been increased by the rise in the price of land in the neighbourhood consequent upon the proposed removal of Charing Cross Station to the south side of the river.

WOMEN DOCTORS AND MARRIAGE.—At the annual meeting of the governors of Birmingham General Hospital last week the following resolution was passed by 22 votes to 16: "That it be made a law of the hospital that, apart from exceptional cases to be determined by the Board, married women shall not be eligible for appointments upon the medical staff, and that women members of the staff who marry during their tenure of office be required to relinquish their position, in view of the disorganisation of the work of the hospital which may be entailed owing to the demands of their domestic duties." The resolution was proposed by a woman member of the Board, who explained that the Board had thrice considered the matter and each time had passed the resolution by a considerable majority. The subject came to a head in consequence of the marriage last year to one of the assistant surgeons of a woman medical officer who, in applying for reappointment to her office, asked for four months' leave of absence as she was expecting to have a baby. The resolution cannot become effective for 12 months, since it must be confirmed at next year's annual meeting.

Correspondence.

"Audi alteram partem."

DISTRICT HOSPITALS AND THE GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—The assumption by the county councils of the management of the district hospitals is likely to lead to changes in the methods and allocation of medical practice, which seem to be in the direction of increasing specialisation, thereby limiting the usefulness of the general practitioner. A questionaire as to the departments in which general practitioners are prepared to coöperate with the activities of the county councils, brings home to every practitioner the possibility that his work with private patients will be curtailed, without any likelihood of his getting, in large centres, much, or any, of the specialist work. Might it be suggested that this is not the most promising way of making use of the general practitioner? He has, while in practice, been acquiring, not special experience in specialist treatment, but special experience in diagnosis. His patients come to him for the relief of disease or disabilities, and it has been his business to find out whether they suffer from complaints which are trivial or temporary, or such that their treatment may be considered a matter of common knowledge, or whether they represent the beginning of more serious ill-health. If the latter, he has endeavoured with some success to learn whether such illness should be treated in hospital or at home, or by some particular specialist. He sends his patients where they are likely to get the advice and treatment which is most likely to benefit them. He does not flood the out-patient department of hospitals or the consulting rooms of specialists with phlyctenular ulcers, or cases of herpes or hydrocele but thinks himself at least equal to the receiving room offices of a hospital in deciding in what department, and from what specialist advice will be best sought. If, therefore he is asked to coöperate, use should be made of his special, rather than of his specialist experience, and he should be asked to undertake the charge of beds in the district hospital. The medical officers to the hospital should be like the surgical medical registrars in earlier days, exercising a general supervision and giving generous help to the house surgeons and house physicians who were in charge of the surgical and medical beds.

With a specialist team behind them, the general practitioners of a neighbourhood, each with a certain number of beds, would do excellent work, and be able to keep in touch with the patients they send to hospital on the one hand, and the work of specialist departments on the other.

Difficulties would undoubtedly arise as they do in teaching hospitals where certain members of the staff do better work than others, but, as in teaching hospitals, they would not be insuperable, and it would be far better for the public that the mistakes which the practitioner commits through want of care or want of knowledge should be committed in the publicity of a hospital ward, rather than in the dim light of a private bedroom.

The present system of having several hundred patients under the charge of a medical officer and two or more subordinates where the usefulness of the medical knowledge existing outside the institution is confined to a rather bitter criticism of facts distorted by the narration of ignorant patients or their friends, should be ended, and the experience of cottage hospitals, where many medical men have charge of patients, may be cited to show how much may be done in this direction to the ultimate advantage of the health of the community.

I am, Sir, yours faithfully,
ROGER N. GOODMAN.

Kingston-on-Thames, March 24th, 1930.

ÆTIOLOGY OF ENCEPHALOMYELITIS FOLLOWING SMALL-POX.

To the Editor of THE LANCET.

SIR,—The real difference of opinion between Prof. McIntosh and Dr. Scarff on the one hand and most other observers including myself on the other depends largely on the interpretation of the histological pictures in the encephalitis produced in animals by the virus of vaccinia and the disseminated encephalomyelitis following vaccination, small-pox, measles, antirabic treatment, &c. in man. Prof. McIntosh bases his view that post-vaccinal and post-smallpox encephalitis are directly due to the virus of the exanthem on the alleged similarity of the cellular reaction in the two types of encephalitis mentioned above, and his contention that the perivascular demyelination of the latter "is rather a sign of severe intoxication and is not specific" is placed on record in his last article on the subject (THE LANCET, March 22nd, p. 621). In a paper forthcoming shortly in the *Journal of Pathology and Bacteriology*, Dr. Fairbrother and I show that the cellular reaction in experimental vaccinial encephalitis is totally different from that in post-vaccinal encephalitis; moreover, in common with the majority of neuropathologists, I believe that the perivascular demyelination of the latter disease is the primary and essential feature and that the cellular response (microglial) is conditioned by the destruction of these fatty sheaths. No worker with the virus of vaccinia has up to the present time succeeded in reproducing experimentally this demyelination, and much other evidence (particularly the peculiar grouping and not infrequent familial occurrence of cases) is available to show that, while the virus undoubtedly plays some part in the ætiology of post-vaccinal encephalitis, it is not directly responsible for the condition. I maintain therefore that at the moment we are justified in seeking some additional factor, which may or may not be a virus, to account for these cases. To me the problem seems comparable with that of disseminated sclerosis following an acute infection to the direct action of which it can hardly be attributed; examples of a disseminated encephalomyelitis similar to that occurring in the course of vaccination, measles, and so forth but arising independently are known.

I am, Sir, yours faithfully,
March 25th, 1930. E. WESTON HURST.

COMPULSORY TREATMENT OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—I am afraid that Miss E. O. Grant, secretary of the British Social Hygiene Council, has missed the point of my communication published in your issue of Jan. 18th (p. 159). In her letter in the following issue (p. 213) she quotes the resolutions of her executive committee, which show that the Council takes a non-committal attitude with regard to the compulsory treatment of venereal disease. They are, of course, perfectly right in taking this attitude, but I desire, with great respect, to point out that this has no bearing on my contention that the medical advisers of the Scottish corporations were not justified, in the light of recent observations, in again urging these bodies to obtain statutory powers to enforce a certain course of treatment even on defaulters, particularly in syphilis. The investigations quoted in my letter showed that there was good reason to believe that such measures were not devoid of risk, and that there was evidence that the multiple fractional doses used in modern antisyphilitic therapy have been followed by an increased incidence of vascular and visceral manifestations.

My contention is—and I feel sure it will be generally supported—that it is imperative to institute an independent inquiry to decide whether these observations are correctly interpreted. I suggested that these investigations should be on the lines so ably that the officials charged with maternity questions, Sir George Newman and the chief officials of the Ministry, should run about the country all day long; that was not the business of chief officers.

Lieut.-Colonel **Ruggles-Brise** said that Parliament would be making a great mistake if they tried to set up a machine closely following on all the other lines of bureaucratic machinery to which they were accustomed, and which might be quite good in many other ways. A special measure of elasticity was necessary in this connexion, because the machine of the Board of Control had the power of dealing with matters affecting the liberty of the subject, a power to which there was no analogy in any other machine or department of State.

After further debate,

Amateur Bureaucracy.

Mr. **Greenwood** said that the proposal in the Bill was to make the machine of the Board of Control effective. The proposal of the amendments was to extend bureaucracy.

Lieut.-Colonel **Fremantle**: Anti-bureaucracy.

Mr. **Greenwood** said he would have thought that the worst kind of bureaucracy was amateur bureaucracy. After going into this matter with great care the Royal Commission felt that what was wanted was a small expert body of people with medical and legal knowledge and administrative experience. That was being provided for in the Bill. The addition of more lay members of the Board would not get rid of the Minister of Health's official responsibility for being the spokesman of the lay mind and of public opinion in these matters. He found it difficult to understand any real justification for either increasing the size of the Board or for adding unpaid members to it. He hoped, therefore, that the Committee would agree to Clause 11 and to the amendments which he (Mr. Greenwood) had put down designed to secure more effective working, and which had been put down after discussion with the Treasury.

After further debate,

Lieut.-Colonel **Fremantle** said that unless the Minister was prepared to reconsider this matter it would be raised again both in and out of Parliament during the remaining stages of the Bill.

Mr. **Greenwood** said that he was sorry that Colonel Fremantle had sounded so fierce when he expressed the desire to fight this matter through. There was very little on which to fight in view of the specific recommendation of the Royal Commission.

The Committee having rejected Colonel Fremantle's amendment to increase the number of the Board from four to six by 19 votes to 8, Miss Lawrence's original amendment was agreed to.

"Senior Commissioners."

Miss **Lawrence** moved an amendment to the effect that the members of the Board of Control should be styled "senior commissioners." She explained that this was the first of a set of amendments, the object of which was to meet the proposal that the senior commissioners, who were themselves appointed by the Crown, should appoint assistant commissioners to carry out the work of visitation. That work would be directly under the senior commissioners.

Lieut.-Colonel **Fremantle** said that he and his colleagues were not opposed to this proposal, though they were to some of its implications. He would reserve comment on that, however, until a later stage.

The amendment was agreed to.

Lieut.-Colonel **Fremantle** moved an amendment to provide that there should be at least two medical commissioners, and that one should be a woman registered medical practitioner. He said that if the Board of Control were going to be mainly glued to their office seats in Whitehall it would obviously be necessary that they should be possessed of the kind of experience necessary for them to fulfil their functions. There were two entirely different lines of work in the medical profession; one was institutional and the other scientific. The two did not work freely together in the higher offices. A man was devoted to scientific work or administration. Very few men in this country could combine the two. The Royal Commission had abundant evidence which they felt justified in bringing into their conclusions that it might be desirable to have two medical commissioners. It was quite open, without any expansion of the Board, to say that two out of the five commissioners should be medical. He excluded the chairman and the legal commissioner; but of the remaining three his amendment proposed that two should be medical and one a woman practitioner. This was put forward strongly by the Medical Women's Federation and various bodies speaking for women doctors, and by some of the mental welfare societies as well. He did not think it was put forward by the medical superintendents and the societies representing them, as they were a male body, but the proposal was supported by women generally, and especially by medical women.

Miss **Lawrence** said that they did not want to make the Board too big. The Government were proposing one more member than the Royal Commission recommended, and they thought that on balance, having regard to efficiency and expense, that that was enough, and they left the fourth commissioner unearmarked. That commissioner might be any person of merit suitable for the position.

The amendment was negatived.

The Committee adjourned.

The Mental Treatment Bill was further considered by Standing Committee A of the House of Commons on Tuesday, March 25th. Mr. **Cecil Wilson** was in the chair.

Reorganisation of the Board of Control.

On Clause 11 Lieut.-Colonel **Fremantle** moved an amendment to provide that all the commissioners of the Board of Control should be appointed by the Crown on the recommendation of the Lord Chancellor or the Minister of Health in the manner proposed in regard to the five senior commissioners. He said that it was proposed that the junior commissioners should be appointed by the senior commissioners. This would mean that when these officials visited the various mental institutions of the country they would carry less weight than if they had been appointed by the Crown. This would be a disadvantage, because it was desirable that the commissioners who visited these institutions should possess the greatest amount of authority possible.

Miss **Lawrence** (Parliamentary Secretary to the Ministry of Health) said that this amendment struck at the whole plan of reorganisation of the Board of Control proposed in the Bill. The idea was to secure a small body of senior administrative officers who would be appointed by the Crown, and that there should be a number of junior commissioners, but nevertheless important officials, who would work under the Board exactly as was the case in any well-conducted Civil Service department. The present Board of Control had been found to be an unwieldy body. She could not accept the amendment.

Dr. **Vernon Davies** said that it was not desired to interfere with the departmental control of the Minister. The whole point was the status of these junior commissioners in the eyes of the heads of the mental institutions which they would have to inspect. Some of those superintendents were most eminent alienists and psychologists of world-wide repute, and they ought to be visited by officials of somewhat similar status.

Dr. **Morris-Jones** said that he did not think there were any insuperable difficulties in the way of accepting this amendment. Mental disease was not in the same category as other branches of medicine, and these junior commissioners would be called upon to meet men in the very front rank of the medical profession in respect of their knowledge and experience of mental disease. There could be no doubt that they would suffer in prestige if it was known that they were appointed by the senior commissioners, and not by the Crown. He thought that the amendment would strengthen the Bill.

Dr. **Vernon Davies** appealed again to the Minister to accept the amendment.

Mr. **Greenwood** said that the logic of this amendment was that everyone who did the work of visiting institutions should be appointed direct by the Crown. He thought that no case had been made out.

The amendment was negatived by 17 votes to 7.

Legal Senior Commissioners.

Miss **Lawrence** moved an amendment providing that no person should be appointed a legal senior commissioner unless either: (1) he was a practising barrister or solicitor of at least five years' standing; or (2) he was a commissioner, other than a senior commissioner, and was, at the date when he was appointed such a commissioner, a practising barrister or solicitor of at least five years' standing; and no person should be appointed a medical senior commissioner unless he was a registered medical practitioner of at least five years' standing.

Dr. **Morris-Jones** moved an amendment to the amendment providing that no medical senior commissioner should be appointed unless he was a registered practitioner of at least seven years' standing. He said that it was quite wrong that it should be possible for a young man of 26, with only five years' experience, should be qualified for appointment as a senior medical commissioner of the Board of Control.

Miss **Lawrence**, in resisting the amendment, said that she regarded it as a frivolous one.

Dr. **Morris-Jones** protested against the remark of M[illegible] Lawrence. He was very anxious to see the Bill become law.

The amendment was negatived.

Dr. **Vernon Davies** moved an amendment to the amendment that no medical commissioner should be appointed who had less than five years' experience of psychological medicine.

Miss LAWRENCE said that she was afraid that this amendment would narrow the field of choice too much. There were very distinguished superintendents of hospitals of vast experience who had not had this amount of practice in psychology. It might therefore exclude people of great professional standing. She would refer the point to the Minister, but she could not accept the amendment at that stage.

Dr. MORRIS-JONES said he hoped that the amendment would not be accepted. It was too drastic.

The amendment was withdrawn.

Miss LAWRENCE's original amendment was then agreed to.

Unpaid Commissioners.

Miss LAWRENCE moved an amendment providing that after the commencement of the Act (1) no further unpaid commissioners should be appointed; (2) the paid commissioners, other than senior commissioners, should be appointed, subject to the approval of the Minister, by the Board of Control and any commissioners so appointed.

Lieut.-Colonel FREMANTLE expressed regret at the abolition of the unpaid commissioners. Such action, he said, would lower the status of the Board.

Miss LAWRENCE said that she could not give a promise on the matter, but she would consult with the Minister in order to see whether a place could not be found for unpaid commissioners among the officers of the Board, but not among the senior commissioners.

Miss PICTON-TURBERVILLE moved an amendment to provide that the officers of the Board should include a woman.

Miss LAWRENCE said that this point would be met on the Report stage.

Lieut.-Colonel FREMANTLE moved that the salary of no commissioner should exceed £3000 per annum. He said that he moved this in order that the Minister might make a statement on the subject.

Miss LAWRENCE assured Colonel Fremantle that the Minister was fully alive to the necessity for giving an adequate, honourable, and attractive salary to the people who would do this important work.

The amendment was negatived.

Clause 11 was added to the Bill.

Clause 12 (Administrative provisions) and Clause 13 (Provision as to the exercise of powers of visitation and inspection) were also added to the Bill.

Transfer of Certain Power from the Minister of Health to the Board of Control.

On Clause 14 Mr. WOMERSLEY moved the following proviso:—

> "Any local authority dissatisfied with any decision of the Board of Control affecting such authority, or with the refusal or withholding of any approval of the Board of Control for which such authority had applied, may appeal to the Minister of Health and any decision or approval given by the Minister on such appeal shall be equivalent to the decision or approval of the Board of Control."

Mr. GREENWOOD, in resisting the amendment, said that it introduced unnecessary machinery into the Bill. No question of general policy was involved under this clause. If such a question arose it would certainly be dealt with by the Minister of Health. The new unification of procedure would bring the Board of Control more directly into contact with the local authorities, but this amendment would drive in a wedge and set the Minister against the Board of Control. That, he was sure, was not the desire of the Committee.

Mr. WOMERSLEY said that he was unrepentent about this matter, and the more he heard it discussed the more he believed in the soundness of the amendment.

The amendment was rejected by 15 votes to 0.

Clause 14 was added to the Bill.

The Committee adjourned.

SHOPS (HOURS OF EMPLOYMENT) BILL.

In the House of Commons on Friday, March 21st, Mr. FREDERICK HALL, in moving the second reading of the Shops (Hours of Employment) Bill, said that the measure provided for a 48-hours week, exclusive of meal times. The shops would be able to keep open for practically the [illegible] hours as at present.

[illegible] R. A. TAYLOR seconded the motion.

[illegible] GERVAIS RENTOUL moved the following amendment:—

> "[illegible] this House declines to give a Second Reading to a Bill [illegible]ld adversely affect the livelihood of a large number of [illegible]ers and shop assistants, would inevitably add to the [illegible]ing, would give rise to widespread evasion, and would [illegible] practical difficulties of administration."

[illegible] CAZALET seconded the amendment.

After further debate,

Dr. ETHEL BENTHAM said that for many years she had been a panel practitioner, having on her list large numbers of men and women engaged in all London trades, and she could say that the health of the shop assistants compared extremely badly with that of people in almost any other trade of which she knew anything. Shop assistants suffered a great deal from varicose veins, flat-foot, and all the disabling things which made life a misery. They aged very early, and broke down very early. With regard to women the matter was even more important and vital. She had no hesitation in saying that the real reasons for these excessively bad conditions of health were to be found in the excessively long hours worked in shops, and the bad ventilation of the premises. There was a greater necessity for protection for this class of worker than for any other within her experience, except perhaps miners.

After further debate,

Mr. A. SHORT (Under Secretary for the Home Office) said that in the view of the Government there was a case for legislation in this connexion, but the information at their disposal was not sufficient to enable them to deal with the situation. They therefore proposed, if the promoters of the Bill were willing, that if the House gave this Bill a second reading an inquiry should be set up on the subject, and the Home Secretary was willing to consult the promoters as to the form and the nature of that inquiry. This was not a device for delay.

Sir G. RENTOUL withdrew his amendment, and the second reading of the Bill was agreed to.

ARMY MEDICAL SERVICE.

On Monday, March 24th, on the motion that the House go into Committee on the Army Estimates for 1930,

Mr. T. SHAW (Secretary of State for War) expressed his regret that there was a shortage of medical men who were prepared to undertake a career in the army. Although the physical tests had been scaled down, the army as a whole was still under establishment. Out of a total of 72,268 recruits who presented themselves for enlistment in 1929, 28,131, or 39 per cent., were accepted, which meant that 61 out of 100 were rejected even on the standards now insisted on. Of the rejections, 91 per cent. were on physical and medical grounds. The lowering of the dental standard, which had previously been tried in Scotland, was extended to England and Northern Ireland, and by that means an additional 2384 recruits were enlisted for all arms. In December, 1928, the height standard for the infantry lines was lowered to 5 feet 2 inches, and 907 young men of suitable physical development were enlisted. By those measures 3219 recruits were accepted who would otherwise have been lost to the service. Without them, the intake for 1929 would have been only 24,840. The physical condition of the young men who presented themselves was a very serious matter, and he was asking his staff to investigate, so far as they could, how far that physical deterioration was due to industrial depression or to other causes.

WORKMEN'S COMPENSATION (SILICOSIS) BILL.

In the House of Lords on Tuesday, March 25th, Earl RUSSELL introduced the Workmen's Compensation (Silicosis) Bill, which was read a first time.

HOUSE OF COMMONS.

THURSDAY, MARCH 20TH.

Teaching of Hygiene in Elementary Schools.

Sir JOHN GANZONI asked the President of the Board of Education whether he was aware that the chief medical officer of the Board had asked the school medical officers throughout the country to submit to him a report upon the teaching of hygiene in public elementary schools; and if the right hon. gentleman would give directions that in future the local education authority and not its officers should be requested to furnish such reports.—Sir CHARLES TREVELYAN replied: There has been some misunderstanding in regard to the circular referred to. It has, however, been made clear by a subsequent communication to the school medical officers that the inquiry was concerned with the medical effect of the teaching of hygiene in the schools. It has been a practice of many years' standing for the chief medical officer to communicate directly with his colleagues in the school medical service in regard to questions on which their professional opinion is desired.

The Ringlemann Smoke Test.

Dr. HASTINGS asked the Minister of Health whether he would be prepared to approve by-laws under Section 2, Subsections (1) and (2), of the Smoke Abatement Act, 1926, defining noxious smoke as smoke of some specified density as measured by the Ringlemann test, which had been used for many years in the United States of America.—Mr.

Greenwood replied: I am aware that in some places in the United States this test has been used, but no local authority in this country has proposed to embody it in by-laws under the Act of 1926 and, as at present advised, I do not think it is suitable for that purpose.

Cardiff City Council and the Schick Test.

Mr. Freeman asked the Minister of Health whether his attention had been called to a proposal of the Cardiff city council to perform the so-called Schick test and inoculate 10,000 healthy children who were under 10 years of age; and, seeing that it was impossible to give an assurance that the immunisation of such a number of children would greatly reduce the incidence of diphtheria and that no compensation was payable, would he see that parents and guardians were informed in writing at least one month before such operations were allowed to take place, and permission in writing was obtained to proceed with the operation on behalf of each child beforehand.—Mr. Greenwood replied: I am aware that this council has offered to protect about 10,000 children against diphtheria by a process of immunisation. I understand that it is the practice of the council to allow parents a reasonable period in which to decide whether they will accept the offer, but that it is not administratively convenient to give as long notice as one month. Permission in writing is obtained from the parent or guardian of each child before it is treated under the arrangements made by the council.

Medical Officers and Municipal Disabilities.

Lieut.-Colonel Fremantle asked the Minister of Health if he would introduce a short indemnifying Bill to exempt present sitting medical members of county and county borough councils from their disabilities to act as from April 1st next during the remainder of their present period of office, pending the reconsideration or reorganisation of the methods of payment to medical practitioners for minor medical services rendered on behalf of local authorities in the course of their private practice.—Mr. Greenwood replied: I regret that I am not able to comply with the suggestion.

Lieut.-Colonel Fremantle asked the Minister of Health if he was aware that in rural parts of the country generally, and particularly in such rural counties as the county of Huntingdon, all practising medical practitioners were rendered ineligible for service as members of county councils by the provisions of the Local Government Act, 1929, and that, therefore, such councils as desire to have medical members, whether coöpted or elected, for their public health, maternity and child welfare, and Midwives Acts, mental deficiency and other committees, were unable to obtain them; and would he take this question into consideration.—Mr. Greenwood replied: Legislation would be required to deal with the matter raised by the hon. and gallant Member, and I am afraid that I can give no undertaking as to such legislation.

Lieut.-Colonel Fremantle: If a one-clause Bill is introduced to remove any inconvenience temporarily, and enable these officers to carry out their duties during the remainder of their term of office, which is obviously desired by the electorate, will the right hon. gentleman try to give facilities for its passage?

Mr. Greenwood: There are only 11 days to go before the new Act comes into operation, and the local authorities have already made their arrangements.

Lieut.-Colonel Fremantle: A great deal can be done in that time.

The Royal Veterinary College.

Captain Crookshank asked the Minister of Agriculture if he could make any statement regarding the Royal Veterinary College.—Mr. Buxton replied: The Development Commissioners have recommended, and the Treasury has approved the recommendation, that, subject to certain conditions, a grant not exceeding £100,000, on a pound-for-pound basis, should be made to the Governors of the Royal Veterinary College for the reconstruction of the College on the present site.

The Hospital at Kuala Lumpur.

Mr. Wellock asked the Under Secretary of State for the Colonies when it was proposed to complete the hospital at Kuala Lumpur; and what sum had been allocated to this purpose in the current estimates by the Government of Malaya.—Dr. Shiels replied: I understand that plans for the new hospital are now under consideration, and though it is possible that the work of construction may begin in 1931, no date has been fixed for completion. No provision has been made in the current estimates.

General Medical Council and Indian Degrees.

Mr. Freeman asked the Secretary of State for India whether his attention had been called to the fact that Indian medical degrees were not recognised by the British Medical Council; and if he proposed to take any action in the matter.—Mr. Wedgwood Benn replied: I am aware that the General Medical Council have withheld recognition of Indian degrees. I am in communication with the Government of India on the subject, and am not at the moment prepared to make any statement. I need hardly say that I am most anxious that a settlement should be reached.

Medical Officers in the Navy.

Dr. Vernon Davies asked the First Lord of the Admiralty if he would give, for each of the last 10 years for which statistics were available, the total number of medical officers in the navy, and the number who joined and the number who left the service in each year.—Mr. Ammon (Parliamentary Secretary to the Admiralty) replied: The figures are as follows:—

Year.	Total medical officers.	Entered.	Retired, &c.	Year.	Total medical officers.	Entered.	Retired, &c.
1920	454	24	29	1925	390	29	32
1921	429	12	37	1926	390	30	30
1922	415	24	38	1927	381	37	46
1923	392	14	37	1928	390	45	36
1924	393	33	32	1929	372	19	37

The total numbers of medical officers are those arrived at by the end of each year. Temporary surgeons entered during the war have not been included, and none are now serving.

Medical Officers in the Royal Air Force.

Dr. Vernon Davies asked the Under Secretary of State for Air if he would give for each of the last ten years for which statistics were available the total number of medical officers in the service, the number who joined, and the number who left the service in each year.—Mr. Montague replied: The following are the figures required in respect of the years for which statistics are available:—

Year beginning April 1st.	Strength beginning of year.	Joined during year.	Left during year.	Year beginning April 1st.	Strength beginning of year.	Joined during year.	Left during year.
1921	119	32	18	1926	188	21	25
1922	133	45	13	1927	184	29	20
1923	165	29	15	1928	193	17	20
1924	179	27	19	1929	190	17*	20*
1925	187	22	21				–

* Figures to date, March 19th, 1930.

Monday, March 24th.

Indian Medical Degrees.

Lieut.-Colonel Fremantle asked the Secretary of State for India if his attention had been drawn to the action of the Indian university authorities which prevented the General Medical Council from being in a position to guarantee the standard of Indian medical degrees and to recognise them for registration on the general medical register: if he was aware that such action would bar future holders of these degrees from the main field of medical practice outside India: and if he would take steps to ensure a reasonable settlement of the question at an early date.

Major Graham Pole asked the Secretary of State for India what action the Government of India proposed to take following the refusal of the British Medical Council to extend recognition to Indian medical degrees; and whether it was now the intention of the Government of India to introduce into the assembly during the present session legislation embodying proposals for the early establishment of an All-India Medical Council.—Mr. Wedgwood Benn replied: I explained the general position in reply to Mr. Freeman on March 20th. I am aware that the decision of the General Medical Council will prevent holders of Indian medical degrees gained during the period of non-recognition from practising in this country. The Government of India informed me on Jan. 6th that they did not expect to be able to introduce legislation for the establishment of a General Medical Council in India during the present session of the Indian Legislative Assembly, and I have not heard from them since on this point.

Lieut.-Colonel Fremantle asked if the right hon. gentleman was taking steps to ask the Government of India if they would agree provisionally to make arrangements so that Indian gentlemen who were qualifying for practice during the next six or twelve months might not be finally and for the rest of their lives debarred from practice?

Mr. BENN said that those were naturally matters on which he was consulting the Government of India.

Dr. VERNON DAVIES asked if Mr. BENN was aware that the cause of the dispute was the alleged statement that the training of the Indian medical gentlemen was not considered sufficient.

Mr. BENN said that it would not be suitable, in reply to a supplementary question, to deal with the whole question of medical training.

TUESDAY, MARCH 25TH.

Indian Medical Research Institute.

Major GRAHAM POLE asked the Secretary of State for India what was the present position in respect of the proposal of the Government of India to remove the Indian Central Medical Research Institute to Debra Dun.—Mr. WEDGWOOD BENN replied: I am sending my hon. friend a copy of a debate in the Indian Legislative Assembly on Feb. 8th from which he will see that the decision to locate the Institute at Debra Dun is to be reconsidered.

Obituary.

JOHN GREGORY WHITE, M.D. EDIN.

Dr. Gregory White, so long a leading practitioner in Bournemouth, died at Aspley Guise, Bedfordshire, on Feb. 11th, at the advanced age of 92. An Edinburgh student in the 'fifties he qualified in 1862, and held resident appointments at the Leith Casualty and Fever Hospitals before settling at Bournemouth, where for many years he had a large and varied practice. The district was then developing rapidly as a winter resort for invalids, among whom Dr. White found scope for his sagacity and practical skill in treatment, combined with the kindliness and patience to which one of his colleagues bears witness. On his retirement in 1907 he went to live at Aspley Guise, where he had inherited property, leaving his practice to his son, Dr. Edward How White. His wide intellectual interests acquired for him a large circle of friends in Bedfordshire, among whom his death is greatly regretted; and there are still many among the senior members of the profession, and of the older residents of Bournemouth, who cherish his memory with affection.

RICHARD HERBERT VERCOE, B.A. CAMB., M.R.C.S. ENG., D.P.H.

Dr. Vercoe, who died at Chelmsford on March 23rd n his fiftieth year, was medical officer of health and school medical officer to the borough. After graduating at Cambridge, Dr. Vercoe continued his medical studies at University College, London, and took the conjoint qualification in 1910. He then held a series of resident appointments at the Prince of Wales's Hospital, Tottenham, and was clinical assistant at the Brompton Hospital. During the war he served n the R.A.M.C., gaining special experience of trench fever, on which he contributed an appendix to Byam's monograph. After taking the diploma in public health at Oxford he was appointed school medical officer at Colchester, where he made a study of the health of school-children in relation to their position in the family which excited a lively correspondence in our own columns. At Chelmsford much of his spare time was occupied with an investigation into the incidence of rheumatism in the school population and the relative importance of heredity and home environment. The mayor of Chelmsford has testified to his value and efficiency as a health officer.

ENLARGEMENT OF CHESTERFIELD HOSPITAL.—The waiting-list being now in excess of 500 it has been decided to erect a new ward at a cost, including equipment, of about £17,000. The basement is to be converted into an eye, ear, and throat department with a small theatre The money for these extensions is in hand, thanks to a egacy of £10,000 and the receipt of £1514 from a carnival.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the undermentioned subjects:—

Surgery.—J. Gordon, T. C. Keble, A. R. Madden, and C. J. Nicol, St. Mary's Hosp.; S. E. Paterson, Edinburgh; A. Scher, London Hosp.; E. M. M. Shaw, Westminster Hosp.; C. Skinner, Guy's Hosp.; and L. J. P. Soromenho, Lisbon and St. Bart.'s Hosp.

Medicine.—T. Chandrasekharan, Madras and Manchester; H. C. Halge, St. Mary's Hosp.; A. Hamid, Middlesex Hosp.; E. G. Nair, Madras and Manchester; R. Nandlal, Birmingham; M. S. Rappoport, London Hosp.; T. Singh, Charing Cross Hosp.; and G. K. Wilsker, Liege and Royal Free Hospital.

Forensic Medicine.—K. Graftdyk, Leeds; H. C. Halge, St. Mary's Hosp.; A. Hamid, Middlesex Hosp.; B. T. W. Harvey, London Hosp.; E. Jacomb, Charing Cross Hosp.; M. S. Rappoport, London Hosp.; and T. Singh, Charing Cross Hosp.

Midwifery.—E. A. Freywirth, Heidelberg and Westminster Hosp.; K. Graftdyk, Leeds; J. M. L. Love, St. Mary's Hosp.; L. R. C. Rose, Manchester; Grantley Smith, Bristol and Guy's Hosp.; and L. C. H. Sykes, Leeds.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: T. Chandrasekharan, J. Gordon, K. Graftdyk, H. C. Halge, A. Hamid, B. T. W. Harvey, R. Nandlal, M. S. Rappoport, A. Scher, T. Singh, C. Skinner, and L. J. P. Soromenho.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

M.CH.ORTH.

M. G. Kini and D. W. L. Parker.

FINAL EXAMINATION FOR M.B. & CH.B.

Part I. (1923 regulations).—A. M. Russell.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part A.—A. J. Galustian, J. M. Grieve, G. W. Phillips, R. Y. Stones, and T. M. Tso.

Part B.—A. J. Galustian, J. M. Grieve, M. J. McHugh, G. W. Phillips, R. Y. Stones, and T. M. Tso.

DIPLOMA IN PUBLIC HEALTH.

Part I.—J. H. St. B. Crosby, H. R. Dugdale, H. P. Fowler, J. D. A. Gray, E. Hughes, H. S. Lawrence, J. S. Mather, E. S. R. Menon, J. W. Pickup, W. J. Pierce, J. H. Pottinger, and Nora M. Wilson.

DIPLOMA IN TROPICAL MEDICINE.

G. R. Baxter, C. J. Boyd, J. A. K. Brown, A. Cathcart, T. T. M. Chen, Ariel R. S. Deacon, J. H. Dobbin, F. D. Gillespie, S. C. Grant, R. Green, M. L. Gulatee, R. A. Heatley, B. N. Khanna, D. K. L. Lindsay, J. E. D. Mendis, M. B. Mody, G. B. Mobile, S. Narain, C. J. Poh, L. Sumitra, and T. Wilson.

DIPLOMA IN TROPICAL HYGIENE.

R. A. Anderson, C. G. Booker, W. A. Bullen, R. Krishna, C. N. Latham, J. E. McMahon, and A. Reid.

UNIVERSITY OF DUBLIN.—At recent examinations in the School of Physic, Trinity College, Dublin, the following candidates were successful:—

M.D.

Wentworth Alexander Taylor.

M.CH.

Gibbon FitzGibbon.

FINAL MEDICAL EXAMINATION FOR M.B., B.CH. & B.A.O.

Part I., Materia Medica, Medical Jurisprudence, Pathology, &c.—*J. A. Wallace, E. F. Burton, P. C. Cosgrove, J. B. Fleming, T. M. R. Ahern, N. H. Leask, H. B. Wright, D. H. S. Boyd, W. A. Hill, H. J. Garland, J. G. Wilson, H. S. Mason, and H. St. G. Smith.

Part II., Medicine.—W. I. Chapman, John Willoughby, Samuel Levy, F. P. FitzGerald, and P. L. O'Neill. *Surgery.*—F. O. Pilkington, R. T. O'Shea, R. E. Hemphill, F. M. Lyons, Arnold Rose, G. F. West, Reginald Bowesman, Patrick O'Shea, E. F. St. J. Lyburn, and Annie E. Thompson *Midwifery.*—*S. H. Moore, *N. A. Kinnear, D. J. O'Ryan, T. A. Bouchier-Hayes, W. A. Robinson, C. H. Adderley, E. S. Duthie, C. H. Hutchinson, C. M. Elliott, Charles Ryan, J. B. Scott, and H. W. Dalton.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

H. M. Fisher, E. T. Mankabadi, Lin Yang, and M. H. Rashwan.

* Passed on high marks.

MANOR HOUSE ORTHOPÆDIC HOSPITAL.—The first sod of the site of the new Manor House Hospital at Golders Green has been cut. The buildings and their equipment will cost £250,000, all of which, with the exception of £22,000, is in hand, and when completed there will be accommodation for 350 patients; there are at present 105 beds. The first of the new permanent buildings will cost £20,500. The hospital is [illegible] the Industrial Orthopædic Society for the [illegible]rial workers.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—The annual congress to be held at the House of the Royal Society of Medicine on Thursday, Friday, and Saturday, April 3rd, 4th, and 5th, under the presidency of Mr. Leslie Paton, is a Jubilee meeting, as the Society was founded in 1880. The following interesting programme has been arranged:

Thursday, 10 A.M. to 12.30 P.M.: Presidential Address, Presentation of the Nettleship Medal. Papers: Mr. E. Treacher Collins, The Harderian Gland, Xerophthalmia, Vitamin A Deficiency, Keratomalacia. Mr. Aykroyd, Night-blindness due to Vitamin Deficiency. Dr. Collier, Ocular Paralyses. Mr. Chavasse, An Examination of Existing Theories of Concomitant Convergent Strabismus, together with Some Observations on the Antiquity of Stereopsis. 2.30 P.M.: Discussion—Disorders of Secretion of the Endocrine Glands Associated with Eye Diseases. Openers: Mr. J. H. Fisher, Prof. H. MacLean, Dr. W. Clark Souter, and Prof. Dodds. The following will take part in the discussion: Messrs. A. W. Ormond, C. Goulden, and others. 9 P.M.: Reception by the President and Council of the Royal College of Surgeons at the College, Lincoln's Inn Fields, W.C.

Friday, 9.30 A.M. to 12.30 P.M.: Papers—Mr. G. F. Alexander, (1) Discission of After-Cataract. (2) An Operation for Aggravated Ectropion. Prof. Van der Hoeve, The Eye and Amnion Bands. Prof. G. Marquez, La Theorie Stereoscopique der Anaglyphes. Dr. Gordon Holmes, Spasm of Fixation. Mr. Ridley, Experimental Investigation into the Intra-Ocular Pressure and the Drainage of the Aqueous. Mr. Doggart, Ocular Rosacea. Mr. Greeves, X Ray Applications in Superficial Keratitis. 2.30 P.M.: Papers—Mr. Juler, Some Cases of Damage to Descemet's Endothelium. Mr. Tudor Thomas, Transplantation of the Cornea (with Demonstration). Dr. Mulock Houwer, The Ætiology of Retention Cysts of the Fornix Conjunctivæ. Mr. Duke-Elder, New Observations on the Physiological Action of the Extra-Ocular Muscles. 4.30 P.M.: Tea. 5 P.M.: The Bowman Lecture—Sir Arthur Keith. The Genius of Bowman. 7.30 for 8 P.M.: Banquet at the Fishmongers Hall, London Bridge, E.C., by courtesy of the Prime Warden and Court. The price of the ticket is £1 15s., and cheques should be sent to Mr. M. H. Whiting, 51, Wimpole-street, London, W.

Saturday, 9.30 A.M.: Papers—Dr. Rosa Ford, The Advantage of Using the Elliot Scotometer at Two Metres. Dr. Adie, Acute Retrobulbar Neuritis in Disseminated Sclerosis. Sir Arnold Lawson, A Further Note on a Case of Bilateral Symmetrical Detachment of the Retina with 6/5 Vision. Mr. Bernard Cridland, Comments on the Certified Causes of Blindness. Miss Ida Mann, The Reptilian Iris. Mr. Basil Graves, Spasmodic Ectropion. 12 noon: Annual Meeting of the Society. 12.30 P.M.: Meeting of British Ophthalmologists. Afternoon: Visit to the Zoological Gardens. Demonstration of Pythons' Eyes with the Slit-Lamp, by Miss Mann. 4.15 P.M.: Tea in the Fellows' Pavilion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An election of three Fellows into the Council will take place at the College in July, the vacancies being occasioned by the retirement in rotation of Mr. R. P. Rowlands, Sir Percy Sargent, and Mr. Victor Bonney, who are all eligible for re-election.

UNIVERSITY OF MANCHESTER.—At a recent examination the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

Part II.—Arnold Brown and J. S. Sewell.

A consultative committee on cancer research, consisting of representatives of the University and of the Manchester Committee on Cancer, including the Christie Hospital and the Radium Institute, has been established. The work will be done at the University laboratories, and will be directed and controlled by the Consultative Committee. Dr. C. C. Twort, who has been working under the direction of the Manchester Committee on Cancer, has been appointed as Director of the Department of Cancer Research.

Mr. John Morley has been appointed lecturer in systematic surgery.

UNIVERSITY OF LEEDS.—The Council has decided to institute a readership in clinical chemical pathology, and Dr. F. S. Fowweather, at present lecturer in chemical pathology, is to be promoted to it. Mr. B. L. Jeaffreson has been appointed tutor in obstetrics and gynæcology, and Dr. J. J. Thomson demonstrator in pathology and bacteriology.

UNIVERSITY OF SHEFFIELD.—The Council of the University has appointed Mr. Graham Simpson to be professor of surgery in succession to Prof. A. M. Connell, who retires from office on March 31st. Mr. Simpson is Senior Surgeon to the Sheffield Royal Hospital.

DEPARTMENT OF HEALTH FOR SCOTLAND.—Dr. Peter L. McKinlay has been appointed a medical officer in this department. A graduate of Glasgow University he was at one time assistant medical statistician to the Scottish Committee upon Problems of Child-life, and for the last five years has been medical statistician on the staff of the Medical Research Council. He has also acted as visiting lecturer to the Division of Vital Statistics and Epidemiology in the London School of Hygiene and Tropical Medicine, and as secretary to the committee on miners' nystagmus.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The meeting of the Maternity and Child Welfare Group, fixed for to-day, Friday, March 28th, is postponed until further notice.

ROYAL STATISTICAL SOCIETY.—The Council of this society will again, in 1931, award a Frances Wood memorial prize, value £30, for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the wage-earning classes.

CITY OF LONDON MATERNITY HOSPITAL.—The Lord Mayor, who last week presided in state over the annual court of governors, stated that the training school had taught 9355 midwives and 15,824 maternity nurses. The rebuilding of the nurses' home, at a cost of £30,000, is said to be overdue.

NORTH MIDDLESEX HOSPITAL.—Last week Mr. Greenwood (Minister of Health) opened the new radium department of this Edmonton hospital, and laid the foundation-stone of an extension of the nurses' home. He remarked that the Local Government Act which is about to come into operation had been passed "with the general approval of public opinion."

POST-GRADUATE COURSES AT DUBLIN.—Arrangements are being made for a three weeks' post-graduate course, on the same lines as in former years, to be held at Trinity College, Dublin, from Sept. 15th to Oct. 4th. A limited number of members of the class can be accommodated in College rooms, or, in the case of women, at Trinity Hall.

CROWDED MENTAL HOSPITALS.—The Corporation of Southend have decided to send the excess of the borough's mental patients to mental hospitals at Exeter and Newcastle-on-Tyne. This action has been caused by the refusal of the committee of the Essex Mental Hospitals to receive more than 175 patients from Southend. The corporation applied to authorities all over the country in the hope of obtaining accommodation, but of the 20 that replied only Exeter and Newcastle had vacancies.

ANCOATS HOSPITAL EXTENSION.—At the centenary, two years ago, of this hospital in the heart of the industrial centre of Manchester, the accommodation was described as "hopelessly inadequate." But the appeal then launched for £100,000 for extensions and improvements has produced only £33,000, and the scheme has therefore had to be seriously modified, and one new block of four wards only will be built. There are at present 114 beds, which it had been hoped to increase to 200, though at least 300 are needed. The number of operations has almost doubled since 1925.

PUBLIC ASSISTANCE IN THE COUNTY OF LONDON.—In accordance with schemes prepared by the Public Assistance and Public Health Committees, the London County Council has allocated the 12 poor-law hospitals which it will take over on April 1st to the five areas into which the capital has been divided for the purpose. In addition, the Council will administer the Queen's Hospital, Sidcup, and Tooting Home Hospital, neither of which is at present in use as a hospital. The Public Health Committee record their belief that "the present available accommodation for the acute sick will be inadequate for future needs."

"HYGIENIC RIGHTEOUSNESS."—At the annual meeting last week of the Royal Hospital, Wolverhampton, Mr. N. B. Graham, the chairman, suggested that patients and prospective patients should be gathered together in the out-patients' hall and instructed in "hygienic righteousness." Last year the average stay in the hospital (5010 patients) was 14·7 days, the cost per head £6 12s. 8½d., an increase of 3s. 2¼d., and per occupied bed £163 15s. 11d., an increase of more than £24 over two years ago. The cost per head at the Women's Hospital was £8 18s. 5½d., and per occupied bed £225 4s. 5½d., a slight increase.

GERMAN SPA CONGRESS.—The Balneological Society of Berlin is arranging to hold its forty-fifth Congress in Bad Elster, Saxony, from April 9th to 13th, under the presidency of Prof. Dietrich. The chief themes for discussion will be the action of iron in medicinal waters, the examination of peat and mud baths, and the dietetics of health resorts. Members will have an opportunity of visiting the University clinics in Leipzig before the congress, and the radium baths at Brambach and Oberschlema afterwards, as well as the sanatoria at Reiboldsgrün and Carolagrün. There is no membership fee and non-members are welcome. Further information from Dr. Max Hirsch, Berlin, W.35, Steglitzerstr. 66.

Manchester Students' Rag.—The Shrove Tuesday "Rag" of the students of the University yielded £10,927, somewhat less than last year's figure, which was £11,013. Street collections raised £1680, and the sale of the "Rag Rag" £5100. Cheques for £1000 apiece have been sent to the Dental Charities' Fund, to the Cancer Research Appeal Fund, and to the Manchester Northern Hospital for Women and Children; the balance goes to the Manchester and Salford Medical Charities' Fund.

"Plymouth Royal Hospital."—It was formally announced at the annual meeting of the South Devon and East Cornwall Hospital that it has now been decided that this institution, the Central, and Royal Albert Hospitals, are to be amalgamated under the above title. A Royal Charter is to be applied for. The South Devon and East Cornwall Hospital is in debt to the bank to the extent of £22,000, and it appears that there is not a grain of radium for hospital use in *Plymouth. The South Devon last year* spent £1000 on treating motor accidents and recovered only £80.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, April 1st.—5.30 p.m., Orthopædics. (Cases at 4.30 p.m.)

Wednesday.—5 p.m., History of Medicine. Papers: Prof. Tom Hare: Two XVIth Century Veterinary Books. Dr. A. P. Cawadias: Epidauros; Some New Photographic Documents. Demonstration: Dr. G. C. Peachey: Frank Buckland at Home. 8.30 p.m., Anæsthetics. Reception at the Wellcome Historical Medical Museum. *During the evening the Rt. Hon.* Lord Dawson of Penn will give an address on Henry Hill Hickman. 8.30 p.m., Surgery. Discussion on Amputations and their Relation to the Artificial Limb. Opener: Mr. C. Max Page. Followed by Mr. P. Jenner Verrall, Dr. R. D. Langdale-Kelham, Captain A. R. Maxwell and others. Illustrative cases will be shown.

Thursday.—8.30 p.m., Tropical Diseases. Paper: Dr. G. W. Theobald: Women, Malaria, and Quinine. Obstetrics and Gynæcology. Members of this Section are specially invited to attend.

TUBERCULOSIS ASSOCIATION. Provincial Meeting at Oxford.

Thursday, April 3rd.—2.30 p.m., The Examination of Contacts. Speakers: Dr. G. Jessel, Dr. N. Bardswell, and Dr. W. Burton Wood.

Friday.—10 a.m., Oleothorax. Speaker: Dr. Gilbert. Demonstrations of Apparatus. 2 p.m., The Economics of Tuberculosis Settlements. Speakers: Dr. P. C. Varrier-Jones, Dr. J. B. McDougall.

Saturday.—10 a.m. (1) Annual General Meeting. (2) Preliminary Reports on Experiences with Turtle-vaccine Therapy. Dr. Fowler and others. (3) Demonstration of Apparatus. The meetings will be held in the Pathological lecture room of the Dunn Laboratory.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, March 31st, to Saturday, April 5th.—Prince of Wales's Hospital, Tottenham, N. Special one week's course in Gastro-Enterology, occupying from 10.30 to 5.30 each day with clinical lectures, demonstrations, operations.—Royal Waterloo Hospital, Waterloo-road, S.E. Special Post-graduate Course in Medicine, Surgery, and Gynæcology. Operations and lecture-demonstrations in the Wards and Out-Patient departments.—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. Special Post-graduate Course of lectures and clinical demonstrations. Daily at 5 p.m.—Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, March 31st.—2.30 to 5 p.m.: Medical, Surgical, and Gynæcological Clinics. Operations.

Tuesday, April 1st.—2.30 to 5 p.m.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

Wednesday.—2.30 to 5 p.m.: Medical, Skin, and Eye Clinics. Operations.

Thursday.—11.30 a.m.: Dental Clinics. 2.30 to 5 p.m.: Medical, Surgical, Nose, Throat, and Ear Clinics. Operations.

Friday.—10.30 a.m.: Throat, Nose, and Ear Clinics. 2.30 to 5 p.m.: Surgical, Medical, and Children's Diseases. Clinics. Operations.

CITY OF LONDON MATERNITY HOSPITA

Tuesday, April 1st.—5 p.m., Mr. R. The Treatment of Disproportion.

CENTRAL LONDON THROAT, NOSE AND EA

Friday, April 4th.—4 p.m., Mr. A. Lownde and Subacute Labyrinthitis.

ROYAL DENTAL HOSPITAL OF LONDON, Leicest W.C.

Wednesday, April 2nd.—6 p.m., Mr. F. P. de Caux: Re Advances in the Methods of Administering N_2O in the Surgery of the Mouth.

ANCOATS HOSPITAL POST-GRADUATE COURSE, Mill-street, Manchester.

Thursday, April 3rd.—4.15 p.m., Dr. N. Kletz: Affections of the Kidneys with Special Reference to Nephritis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, April 1st.—4.15 p.m., Mr. P. R. Wrigley: The Investigation and Treatment of Enlargement of the Prostate.

Friday.—4.15 p.m., Mr. J. P. Buckley: Demonstration of Surgical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, April 2nd.—4.15 p.m. (Victoria Infirmary), Dr. R. M. Marshall: Medical Cases.

Appointments.

Certifying Surgeons under the Factory and Workshop Acts: Smart, J., M.B., Ch.B. Glasg. (Dunoon, Argyll); and Duckworth, H. L. D., M.B., B.Ch. Dub. (Ross, Hereford).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary.—Res. Surg. O. At rate of £200.
Barnsley, Beckett Hospital and Dispensary.—Cas. O. £250.
Bath Royal United Hospital.—H.S. At rate of £150. Also H.P. £120.
Bedford County Hospital.—H.S. At rate of £175.
Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.S. Also Asst. H.P. Each at rate of £100.
Blackburn, Royal Infirmary.—4th H.S. £150–£200.

Notes, Comments, and Abstra

HEALTH AND CLEANLINESS.

Dame Louise McIlroy, speaking at a luncheon give the Health and Cleanliness Council on March 19th, that it was impossible to make people moral by A Parliament, but at least it was possible to make clean. The root of all the excellent work in the welfare campaign was cleanliness; it had led to a redu of infant mortality by almost half the figure at whi had stood a few years ago. She urged all her heare join the campaign against long skirts, lest, sweepin floor like their Victorian grandmothers, women sl again help to disseminate dirt and disease. In mate work many women were still the victims of puer septicæmia, and sepsis was due to matter out of plac dirt. We should pin our faith not to antiseptics bu the cleansing properties of soap and water, and to protective mechanisms of the human organism.

Dr. G. F. Buchan, chairman of the Council, in repl to Dame Louise, said that health and cleanliness indissolubly associated. The basis of all rules for prevention of disease and the preservation of health cleanliness; sanitation aimed at making and keepin towns and houses clean. One of the attributes of be was cleanliness, and just as the æsthetic pleasure Romans took in their baths led them to provide an exce water-supply, so a wholesome vanity and the satisfa inherent in a sense of cleanliness might lead to valu reforms in our own day. It was necessary to stimul public consciousness of cleanliness. The most dange forms of dirt were bacteria; they were constantly dis inated by our fellow men and ourselves, and frequent l could help to prevent the spread of infection. The d rate from typhoid had been reduced enormously by impr sanitation during the last 50 years, by means of whic now enjoyed a clean water-supply. Public swimming b were often a source of infection; no person should such baths without previously washing thoroughly soap and water. Persons with discharges from ear eyes should be forbidden to use them.

A HOSPITAL IN THE ARCTIC.

THE Archdeacon of the Arctic, the Ven. A. L. Flem is trying to raise money to establish a hospital at Harbour, Baffin Land, at the eastern side of the distri Franklin. It was hoped that enough money migh raised to endow a bed in this hospital, to be dedicate "the memory of Sir John Franklin and his compan Sir John Richardson, Sir George Back, Lieutenant Ken &c.," but the number of surviving relatives is too few them to provide the necessary sum.

The fate of the *Erebus* and *Terror* expedition (184 overshadows the results of Sir John Franklin's ea explorations (1819–22 and 1925–27) that it is forgo what important additions they made to the map of Can The former "barren lands" of the first explorers have a continually increasing population of miners, traders, plane and railway employees, as well as settlers with families. Transport is facilitated by air or steamb even in winter communication is carried on by airpla The inhabitants of some of these regions will benefit by Lake Harbour Hospital. North-Western Canada is vided with a hospital at Aklarvik, Mackenzie River, the nursing staff for North-Eastern Canada have volunte and are ready to go as soon as there a building for to work in. Cheques may be made payable to the Ar Hospital Fund," and sent to Miss Gell, Harewood Ho Keyhaven, Milford-on-Sea, Hants.

OFFICIAL YEAR BOOK OF LEARNED SOCIETI

FOR 46 years past Messrs. Charles Griffin and Co. l have compiled from official sources a record of the w done in science, literature, and art during the prece twelvemonth, and have issued it in the Year Book of Scientific and Learned Societies of Great Britain and Irel The present volume is dated 1929 on the cover (althou might fairly be imprinted 1930); it contains 410 pages well printed and indexed, and is issued at 18s. The pub lisher's threat to limit the scope of the year-book by inser lists not of papers read but only those which are publis by the societies in question, which was to have taken ef this year, has been again postponed; but unless their ap for more general support is answered it seems that 47th volume will be issued in the less complete form. publisher sees in this one more illustration of the tend of the times to work less and play more, and we hope foreboding will be disappointed. The volume is a useful one for reference, and should be on the shelve every public library.
